## WikiOracle

Revision: 2026.07.15

### An open-source architecture for truthful AI.

WikiOracle is a truthful, explainable LLM system designed as a public good – the Wikipedia model applied to artificial intelligence.

### The Problem

For-profit corporations are using our data – sourced from billions of people – to train models that are teaching our children. Those models hallucinate, cannot reliably explain themselves, and are vulnerable to ideological capture and data-driven manipulation, especially under online learning. The knowledge they encode is then locked behind proprietary walls.

Most large AI systems are built around a single global objective, centralized data aggregation, hidden alignment rules, and implicit averaging over moral and cultural differences. Minority viewpoints are quietly averaged away, the loudest groups shape the model at scale, and a single model becomes an authority node on which everyone depends. When predictive advantage converts into economic or political dominance, wisdom stops being a shared good and becomes a strategic asset.

## What Makes WikiOracle Different

| Commitment              | Architectural expression                                                                                                                                                                           | Practical effect                                                                                                                   |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Truth</b>            | Claims are explicit TruthSet entries with a Degree of Truth (DoT) on $[-1, +1]$ ; logic and sources remain inspectable.                                                                            | Claims can be contested, revised, and grounded instead of being accepted because they sound fluent.                                |
| <b>Data sovereignty</b> | <code>state.xml</code> holds identity, conversations, and truth; <code>config.xml</code> separates server policy from client preferences. Stateful and stateless runtime modes are both supported. | A user can export, merge, and move a session without depending on hidden central memory.                                           |
| <b>Secure sharing</b>   | Dropbox backup stores AES-encrypted ZIP bundles. A shared state can be represented as an <code>&lt;authority&gt;</code> reference and encoded as a QR code.                                        | Another client can import the shared state and assign its own trust weight without receiving the sender's config or provider keys. |
| <b>Democracy</b>        | Each participant maintains an independent trust map; disagreement among credible sources is represented rather than silently averaged away. Forking is a constitutional right.                     | No company, state, foundation, or maintainer group becomes the universal epistemic root.                                           |
| <b>Distribution</b>     | Authorities contribute remote TruthSets with scaled certainty, while provider entries act as expert consultants in a Hierarchical Mixture of Experts (HME).                                        | Trust is transitive but attenuated, and provider output remains evidence rather than unquestionable authority.                     |

## Current Prototype

| Capability         | Current implementation                                                                                       |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| Conversation model | Branching conversation tree with diamond-shaped merges for provider voting                                   |
| Truth model        | Facts, feelings, references, logic, authorities, and providers in typed XML                                  |
| Reasoning          | Strong Kleene <b>and</b> , <b>or</b> , <b>not</b> , and <b>non</b> operators over DoT values                 |
| Provider layer     | Runtime-selectable WikiOracle/NanoChat, BasicModel, OpenAI, Anthropic, Gemini, Grok, and OpenRouter adapters |
| Learning           | Optional online training constrained by DoT, warmup, clipping, and checkpoint anchoring                      |
| Storage            | Local XML plus optional AES-encrypted Dropbox backup and authority sharing                                   |

| Capability     | Current implementation                                                                             |
|----------------|----------------------------------------------------------------------------------------------------|
| Research scale | Local CPU/MPS workflows and rentable GPU workflows intended for comparatively low-cost experiments |

## Longer-Term Direction

If WikiOracle proves viable at small scale, the architecture can be evaluated with larger open models. The broader aim is to test whether architectural commitments to truth can enable honest self-explanation, reduce reliance on ad-hoc guardrails, and support AI systems that function as durable public goods. Current engineering priorities are tracked in `todo.md`.

## How to Contribute

| Area                        | Examples                                                         |
|-----------------------------|------------------------------------------------------------------|
| ML systems                  | Model integration, training, evaluation, and performance work    |
| Safety and interpretability | Explainability, adversarial analysis, and capture resistance     |
| Epistemology and governance | Philosophy of science, plural truth, and constitutional critique |
| Product quality             | Documentation, UI, accessibility, testing, and deployment        |

## Getting Started

See the Installation Guide for prerequisites, local services, training, and deployment.

```
git submodule update --init --recursive
make install
make nano_restart NANO_MODEL_TAG=d26 NANO_DEVICE_TYPE=cpu NANO_DTYPE=float32
make wo_restart
make nano_status wo_status
```

Then open <https://127.0.0.1:8888> and accept the local development certificate.

## Documentation

The assembled manual is WikiOracle.pdf. Its WikiOracle server and client chapters live in `./doc`:

## WikiOracle

Revision: 2026.07.15

WikiOracle is a local-first orchestration layer for conversations, explicit truth, provider voting, and optional online learning. A browser client owns the interaction model; a Flask shim validates and executes each request; and one or more language-model providers supply responses or evidence.

### Architectural Overview

The durable interchange format is deliberately small: two schema-validated XML documents separate user/session data from runtime policy.

| Document                | Canonical sections                                                                                                               | Owner                                 | Purpose                                                                                                                                     |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>state.xml</code>  | <code>&lt;header&gt;</code> , recursive<br><code>&lt;conversation&gt;</code> elements,<br>optional<br><code>&lt;truth&gt;</code> | Client/session                        | Identity metadata, conversation history, selection state, attachments, and the user's TruthSet                                              |
| <code>config.xml</code> | <code>&lt;server&gt;</code> and optional<br><code>&lt;client&gt;</code>                                                          | Server policy plus client preferences | Runtime mode, truth policy, evaluation and training defaults, provider definitions, UI preferences, provider selection, and client API keys |

The same application supports two runtime contracts:

| Mode             | State authority                                                                          | Request/response contract                                                                       | Writes                                                            |
|------------------|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>Stateful</b>  | Flask shim loads the canonical state file                                                | The client may send truth overrides; <code>/chat</code> returns the selected conversation delta | State and client config may be written locally                    |
| <b>Stateless</b> | Browser supplies authoritative state and runtime config on every <code>/chat</code> call | <code>/chat</code> returns the full updated state                                               | No state or config writes; client data remains in browser storage |

The public `wikioracle.org` deployment uses stateless mode. Local development can use either contract.

## State and Conversation Model

The state grammar is **Header + Conversation\* + Truth?**. Conversations form a recursive tree in XML and may form a DAG in memory when a voting result has multiple parents.

| State unit   | Required content                                 | Important metadata                                                                                               | Role                                                        |
|--------------|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Header       | Version, schema URL, creation time, title        | Last-modified time, client name, client ID                                                                       | Identifies the portable state document                      |
| Conversation | Title plus ordered message/conversation children | <code>id</code> , optional <code>parentId</code> , optional <code>selected</code>                                | Represents a root session, branch, or merge node            |
| Message      | XHTML content and optional attachments           | <code>id</code> , <code>role</code> , <code>username</code> , <code>time</code> , optional <code>selected</code> | Represents a user, assistant, or system turn                |
| TruthSet     | Zero or more typed truth entries                 | Entry IDs, titles, timestamps, place, and DoT where applicable                                                   | Supplies explicit evidence, rules, experts, and authorities |

Selection is persisted on conversation and message elements. Selected conversations form one root-to-node path; a selected message is unique across the state.

## TruthSet

Truth entries are typed XML elements rather than an unstructured prompt appendix.

| Element                   | DoT      | Meaning                         | Evaluation behavior                                                  |
|---------------------------|----------|---------------------------------|----------------------------------------------------------------------|
| <code>&lt;fact&gt;</code> | Required | Verifiable claim or observation | Included as direct truth and eligible for derivation/training policy |

| Element                        | DoT      | Meaning                                                                                | Evaluation behavior                                                     |
|--------------------------------|----------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <code>&lt;feeling&gt;</code>   | None     | Subjective, poetic, or otherwise non-truth-evaluable expression                        | May shape evaluation but is excluded from evidence scoring and training |
| <code>&lt;reference&gt;</code> | Required | External citation represented by one <code>&lt;a href="..."&gt;</code> anchor          | Grounds a claim in an inspectable source                                |
| <code>&lt;logic&gt;</code>     | Required | <b>and</b> , <b>or</b> , <b>not</b> , or <b>non</b> over references or inline operands | Computes derived certainty using Strong Kleene/fuzzy semantics          |
| <code>&lt;provider&gt;</code>  | Required | Dynamic expert definition, optionally conversational                                   | Produces evidence or a visible voting branch                            |
| <code>&lt;authority&gt;</code> | Required | Pointer to another state or TruthSet                                                   | Imports remote truth with certainty scaling and bounded fetching        |

DoT values occupy  $[-1, +1]$ : -1 is certainly false, 0 is unknown, and +1 is certainly true. Feelings intentionally sit outside that truth lattice.

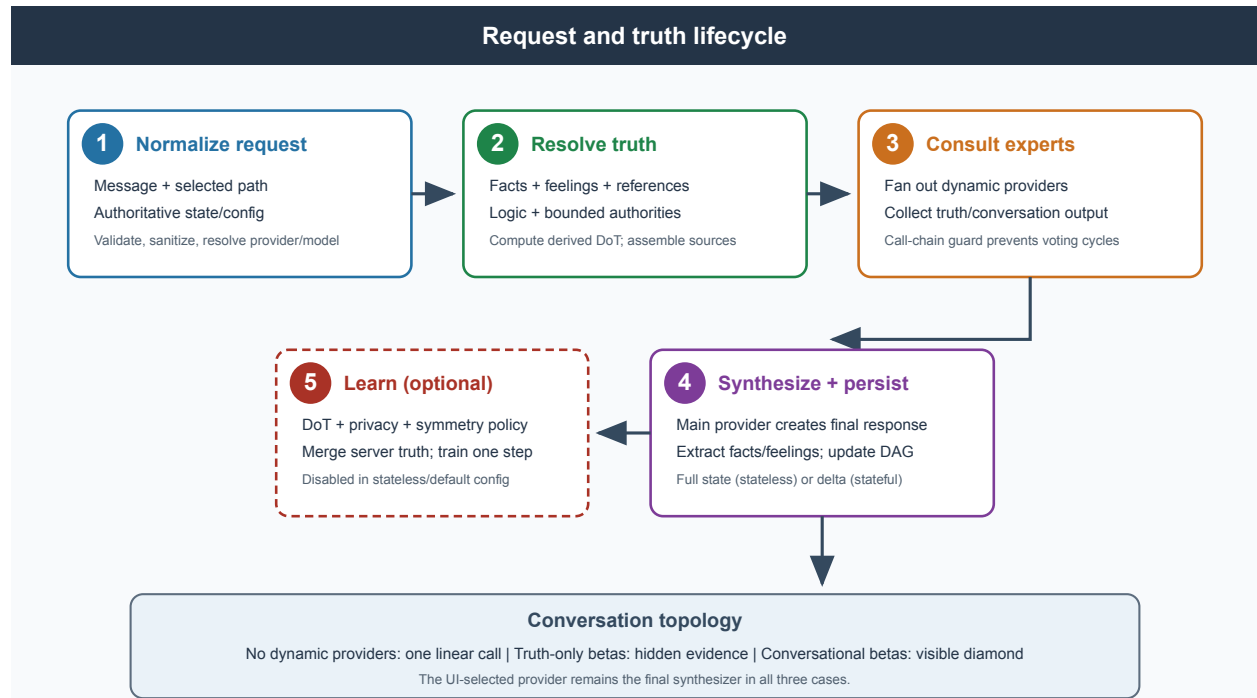

## Configuration Model

The configuration separates fields the operator controls from preferences a client can update.

| Scope                          | Major sections                       | Examples                                                                    |
|--------------------------------|--------------------------------------|-----------------------------------------------------------------------------|
| <code>server</code>            | Identity and mode                    | <code>server_id</code> , <code>stateless</code> , <code>url_prefix</code>   |
| <code>server.truthset</code>   | Truth policy                         | Symmetry checks, concrete-fact storage, truth weight                        |
| <code>server.evaluation</code> | Provider defaults                    | Temperature, maximum tokens, timeout, URL fetching, thought-free mode       |
| <code>server.training</code>   | Online learning                      | Enable switch, corpus path, DoT learning rates, clipping, anchoring, device |
| <code>server.providers</code>  | Provider registry and shared prompts | Provider type, URL, model, timeout, streaming, context/output instructions  |
| <code>client.ui</code>         | Browser preferences                  | Layout, theme, divider position, swipe navigation, confirmation prompts     |
| <code>client.providers</code>  | Client selection and credentials     | Default provider, default model, per-provider API key                       |
| <code>client.storage</code>    | Cloud-storage preference             | Optional state key; Dropbox app credentials remain server-only              |

The server exposes a client-safe projection of config: Dropbox credentials and any legacy server-side provider key are removed. Client-owned API keys remain in `client.providers` because the browser settings flow owns and supplies them; they must therefore be treated as sensitive browser-accessible data.

## Conversation and Truth Pipeline

| Stage               | Inputs                                                                             | Result                                                                               |
|---------------------|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| 1. Normalize        | User message, selected path, runtime config, client TruthSet                       | Valid XHTML, effective provider/model, direct and derived truth                      |
| 2. Consult          | Dynamic provider entries, direct truth, prompt context                             | Conversation contributions and/or truth-only contributions from beta providers       |
| 3. Synthesize       | Selected main provider, history, TruthSet, authorities, derived logic, beta output | Final response plus extracted facts and feelings                                     |
| 4. Persist          | Updated conversation graph and truth policy                                        | Full state in stateless mode or local state plus conversation delta in stateful mode |
| 5. Learn (optional) | Extracted truths, DoT, privacy/symmetry filters, training settings                 | Server truth merge and a bounded online-training step                                |

When no dynamic `<provider>` entries exist, the consultation stage collapses to a single call to the UI-selected provider. When conversational beta providers participate, WikiOracle records their branches and the final synthesis as a diamond in the conversation DAG.

### Provider Voting Example

The HME voting pattern distinguishes the provider that synthesizes the answer from providers that contribute evidence.

| Actor | Input    | Output        | Conversation visibility |
|-------|----------|---------------|-------------------------|
| User  | Question | Query message | Root or selected branch |

| Actor          | Input                                                                        | Output                                               | Conversation visibility                                                                  |
|----------------|------------------------------------------------------------------------------|------------------------------------------------------|------------------------------------------------------------------------------------------|
| Beta provider  | Query, direct truth, and role-specific context                               | Facts/feelings; optionally a conversational response | Hidden when <code>conversation=false</code> ; visible as a branch when <code>true</code> |
| Alpha provider | Query, conversation history, TruthSet, derived truth, and beta contributions | Final answer plus extractable facts/feelings         | Final merge node                                                                         |

Cycle prevention carries a provider call chain through nested consultations. A provider already present in the ancestry remains silent, preventing recursive voting loops. See Voting for the topology and Implementation for the endpoint and module reference.

## WikiOracle Constitution

Revision: 2026.07.15

### Preamble

WikiOracle is an open-source architecture for truthfulness: a way to enlist the power of LLMs while preserving truth in the face of centralized, opaque “global corporate mental models” (including those embedded in proprietary systems).

WikiOracle is the Wikipedia model applied to LLMs:

- anyone can contribute claims, counterclaims, evaluations, and tests
- revision is expected and legible
- provenance and dispute are first-class, not edge-cases

However, it is also distributed, possibly encrypted, and hopefully kind:

- Truth does not need to be centralized to be shared.
- An unempathetic body of truth can be prevented by refusing selfish truths (truth must be universally true).

Truthfulness is not a one-time achievement. It is an ongoing, open engineering and governance effort.

Even if the reasoning machine is large and unified, the data and trust it operates on must remain distributed and under individual control. Epistemic contributions are people-owned and revocable by the data providers. Answers must be conditioned on what each user chooses to trust and believe to be true, not forced into a single impoverished consensus view of reality.

This constitution defines the non-negotiable invariants for WikiOracle’s truth system and for changes to it. Implementation details and deeper theory live in the rest of the `doc/` directory.

### Core Commitments

WikiOracle is architected not merely as a system of prediction, but as a shared epistemic commons. It must:

- Increase collective agency without concentrating domination.
- Represent the concerns of all creatures, not just the operator.
- Preserve truth as a shared human resource.

Therefore:

| Principle                        | Implication                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------------------|
| Truthfulness over fluency        | Prefer grounded, falsifiable, uncertain, or incomplete answers over smooth, unsupported ones.             |
| Truth is not consensus           | A single, averaged narrative is not the goal. The system must preserve real disagreement where it exists. |
| Plural points of view            | Support multiple POVs, each with its own trust map and standards of evidence.                             |
| Transparency by default          | Claims, confidence, provenance, and update rationales must be inspectable and reproducible.               |
| Reversibility and accountability | High-impact changes must be attributable, testable, and reversible.                                       |
| Public benefit and anti-capture  | No single actor (company, state, foundation, or maintainer group) becomes the epistemic root for others.  |

## Truth Primitives (What the System Is Allowed to Believe)

WikiOracle’s truth layer is composed of explicit, user-visible primitives stored in state. All carry a Degree of Trust on  $[-1, +1]$  except feelings, which are orthogonal to the truth lattice.

| Primitive        | Trust value          | Source                      | Role in reasoning                                                                                  |
|------------------|----------------------|-----------------------------|----------------------------------------------------------------------------------------------------|
| <b>Feeling</b>   | none<br>(orthogonal) | user / provider             | Non-falsifiable direct perception. Influences evaluation; never trains.                            |
| <b>Fact</b>      | $[-1, +1]$           | user / provider / authority | Atomic proposition with Fuzzy Kleene certainty (believed / unknown / disbelieved).                 |
| <b>Reference</b> | $[-1, +1]$           | user                        | Pointer to an external object (URL).                                                               |
| <b>Operator</b>  | derived              | user / engine               | Explicit computed relationship: <b>and</b> , <b>or</b> , <b>not</b> , <b>non</b> (Strong Kleene).  |
| <b>Authority</b> | $[-1, +1]$           | user                        | Pointer to a remote knowledge base ( <b>state.xml</b> , ORCID, DID); transitive trust, attenuated. |
| <b>Provider</b>  | $[-1, +1]$           | user                        | External AI used as a tool (“other mind”); its outputs become evidence, not authority.             |

All truth computations must remain legible as operations over these primitives. If the system “knows” something, it should be possible to point to what it is grounded in; otherwise it is merely intuition. See Truth.md.

## Plurality, Dispute, and Minority Preservation

| Rule                        | Mechanism                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| POV-conditioned conclusions | Present conclusions conditioned on the selected POV / trust map.                                    |
| Overlaps are valuable       | When independent POVs converge on a claim, surface the agreement explicitly as a robustness signal. |
| Disputes stay visible       | Where serious disagreement exists, represent the dispute rather than smoothing it away.             |
| Minority protection         | Evidence-supported minority viewpoints must not be excluded by majority preference or convenience.  |

## Independence From Any Single AI Vendor

WikiOracle may use proprietary or open models as providers, but:

| Rule                           | What it guarantees                                                                               |
|--------------------------------|--------------------------------------------------------------------------------------------------|
| No provider is privileged      | Data is revocable and belongs to the client.                                                     |
| Providers are evidence sources | Provider outputs are non-authoritative contributions with a trust value like any other entry.    |
| Replaceability is required     | The system remains operable if any single provider becomes unavailable, hostile, or compromised. |

## Authority Delegation Must Be Bounded and Secure

Authority entries exist to enable decentralized truth (a network of trust) without collapsing into a single global oracle.

| Constraint                     | Detail                                                                                            |
|--------------------------------|---------------------------------------------------------------------------------------------------|
| Trust decreases with every hop | Importing an authority must not recursively fetch authorities of authorities.                     |
| Certainty scaling              | Imported claims are scaled by the authority's certainty (trust is transitive but attenuated).     |
| Namespaced IDs                 | Imported entries are namespaced to prevent collisions and preserve provenance.                    |
| Explicit source selection      | Users (or POV definitions) explicitly choose which authorities to trust; no implicit global root. |
| Operational safety             | Fetching and caching is rate-limited, size-limited, and restricted to safe URL schemes.           |

## Local-First Data and Auditability

| Tier                          | Posture                                                                                            |
|-------------------------------|----------------------------------------------------------------------------------------------------|
| Client-owned Particular State | Default local-first: user conversation state and news live on the user's machine and are portable. |
| Server-owned Universal State  | A shared service accumulates only anonymized knowledge as a TruthSet of trusted facts.             |

See [PrivacyAndSecurity.md](#).

## Safety as Freedom, Empathy, and Truth

WikiOracle's truthfulness effort must not trade away human welfare or agency:

| Pillar  | Commitment                                                                                                                                                                                    |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Freedom | Increase distributed agency, not centralized leverage. AI must not be used to transgress the freedom of others. Data sovereignty is non-negotiable.                                           |
| Empathy | Represent the concerns of all creatures, not just the operator. Preserve dignity, minimize harm, and make uncertainty explicit. De-emphasize egocentric optimization that externalizes costs. |

| Pillar | Commitment                                                                                                                                                                               |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Truth  | Keep truth auditable and non-proprietary; do not convert epistemic advantage into coercive control. Open data formats, open tests, willingly shared truth. Make surveillance impossible. |

See Freedom.md, Ethics.md, and Truth.md.

## Installation

### Environment and System Preparation

#### Requirements

| Requirement                         | Needed for               | Notes                                                                                                                             |
|-------------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Git with submodule support          | All workflows            | Run <code>git submodule update --init --recursive</code> after cloning                                                            |
| Python 3.12 and <code>make</code>   | WikiOracle install/run   | The tracked Makefile creates the shim venv with <code>python3.12</code>                                                           |
| <code>uv</code>                     | NanoChat environment     | <code>make install</code> bootstraps it when absent                                                                               |
| Pandoc + XeLaTeX                    | PDF documentation        | Required for <code>make WikiOracle.pdf</code> / <code>make doc</code>                                                             |
| LibreOffice                         | MOC poster PDF export    | Required by <code>make doc</code> only when the PPTX is newer than the checked-in PDF or the PDF is missing                       |
| AWS CLI                             | EC2 build host           | Required only for <code>REMOTE_PROVIDER=ec2</code> workflows                                                                      |
| Lambda Labs API key                 | Lambda build host        | <code>./lambda-api-key</code> , <code>LAMBDA_API_KEY_FILE</code> , or <code>LAMBDA_API_KEY</code>                                 |
| SSH keys                            | Remote build/deploy      | Lambda ( <code>LAMBDA_KEY_FILE</code> ), EC2 ( <code>EC2_KEY_FILE</code> ), and WikiOracle/Lightsail ( <code>WO_KEY_FILE</code> ) |
| Ignored <code>Makefile.local</code> | Private LAN/tunnel hooks | Holds machine-specific <code>up/down/sync/tunnel</code> targets                                                                   |

#### Python dependencies

`make install` creates both virtual environments and installs all dependencies:

```
make install          # CPU/MPS (default)
make install ARCH=gpu # GPU/CUDA
```

| Environment                 | Contents                                                                  |
|-----------------------------|---------------------------------------------------------------------------|
| <code>.venv</code>          | WikiOracle Flask shim and dependencies from <code>requirements.txt</code> |
| <code>nanochat/.venv</code> | NanoChat runtime managed by <code>uv</code>                               |

#### Data and tokenizer bootstrap

```
make build_data
make build_tokenizer
```

## Environment variables

| Variable              | Default                            | Purpose                                                               |
|-----------------------|------------------------------------|-----------------------------------------------------------------------|
| WIKIORACLE_STATE_FILE | <code>state.xml</code>             | Path to local state file (WikiOracle State XML)                       |
| WIKIORACLE_BASE_URL   | <code>http://127.0.0.1:8000</code> | Upstream NanoChat-compatible base URL                                 |
| WIKIORACLE_API_PATH   | <code>/chat/completions</code>     | Upstream chat path                                                    |
| WIKIORACLE_STATELESS  | (unset)                            | Set <code>truthy</code> to disable all writes and use in-memory state |
| WIKIORACLE_URL_PREFIX | (unset)                            | Optional reverse-proxy path prefix                                    |
| WIKIORACLE_BIND_HOST  | <code>127.0.0.1</code>             | Network interface to bind                                             |
| WIKIORACLE_BIND_PORT  | <code>8888</code>                  | Server port                                                           |

## The Makefile: Running and Building

All local and remote workflows are orchestrated through the Makefile.

### Top-level targets

These are the primary entry points. For a local WikiOracle + NanoChat stack, use `install`, then the `nano_*` and `wo_*` service targets. `build` is still present, but it delegates to `train`, which currently runs the BasicModel training pipeline.

| Target                             | Purpose                                                               |
|------------------------------------|-----------------------------------------------------------------------|
| <code>make install</code>          | Create <code>.venv</code> (shim + NanoChat), install all deps         |
| <code>make build</code>            | Alias for <code>make train</code> (currently the BasicModel pipeline) |
| <code>make nano_train</code>       | Full NanoChat training pipeline                                       |
| <code>make sync HOST=local</code>  | Optional private sync hook from <code>Makefile.local</code>           |
| <code>make sync HOST=remote</code> | Sync app + checkpoints to/from production server                      |
| <code>make sync HOST=build</code>  | Deploy active remote training artifacts to WikiOracle                 |
| <code>make run HOST=local</code>   | Start WikiOracle Flask shim locally (foreground)                      |
| <code>make up HOST=remote</code>   | Restart both services on production                                   |
| <code>make down HOST=remote</code> | Stop both services                                                    |
| <code>make all</code>              | Full pipeline: install + train + eval + report                        |

### Training (`train_*`)

| Target                                                      | Purpose                                                  |
|-------------------------------------------------------------|----------------------------------------------------------|
| <code>make train HOST=local</code>                          | BasicModel training pipeline                             |
| <code>make train HOST=build</code>                          | Launch remote GPU instance, copy repo, start training    |
| <code>make nano_train</code>                                | Full NanoChat pipeline: data + tokenizer + SFT model     |
| <code>make train_pretrain</code>                            | Pretrain base model ( <code>ARCH=cpu gpu</code> )        |
| <code>make train_finetune</code>                            | Supervised fine-tuning ( <code>ARCH=cpu gpu</code> )     |
| <code>make train_deploy</code><br><code>HOST=build</code>   | Launch remote instance, train, then deploy to WikiOracle |
| <code>make train_retrieve</code><br><code>HOST=build</code> | Pull artifacts from build instance, terminate it         |
| <code>make train_ssh</code><br><code>HOST=build</code>      | SSH into running build instance                          |

| Target                                                    | Purpose                             |
|-----------------------------------------------------------|-------------------------------------|
| <code>make train_status</code><br><code>HOST=build</code> | Check build instance state          |
| <code>make train_logs</code><br><code>HOST=build</code>   | Tail training log on build instance |

### Test / Evaluation (`test_*`)

| Target                                                       | Purpose                                                  |
|--------------------------------------------------------------|----------------------------------------------------------|
| <code>make test HOST=local</code>                            | Run WikiOracle + BasicModel tests                        |
| <code>make test_all HOST=local</code>                        | Run WikiOracle + BasicModel <code>test_all</code> target |
| <code>make test_unit</code><br><code>HOST=local</code>       | Run unit tests                                           |
| <code>make test_basicmodel</code><br><code>HOST=local</code> | Run BasicModel tests                                     |
| <code>make test_eval</code><br><code>HOST=local</code>       | Evaluate model ( <code>ARCH=cpu gpu</code> )             |

### Run / Inference (`run_*`)

| Target                                                 | Purpose                                  |
|--------------------------------------------------------|------------------------------------------|
| <code>make run HOST=local</code>                       | Start WikiOracle local shim (foreground) |
| <code>make run_debug</code><br><code>HOST=local</code> | Start WikiOracle local shim (debug mode) |
| <code>make run_init HOST=local</code>                  | Remove state files for a fresh start     |
| <code>make run_cli HOST=local</code>                   | Chat with NanoChat directly (CLI)        |
| <code>make run_web HOST=local</code>                   | Run the NanoChat web extension           |

### Sync (`sync_*`)

| Target                                 | Purpose                                                     |
|----------------------------------------|-------------------------------------------------------------|
| <code>make sync HOST=local</code>      | Optional private sync hook from <code>Makefile.local</code> |
| <code>make sync HOST=remote</code>     | Sync app + checkpoints to/from production server            |
| <code>make sync HOST=build</code>      | Deploy active remote training artifacts to WikiOracle       |
| <code>make sync_checkpoint_pull</code> | Pull fine-tuning weights from production                    |
| <code>make sync_checkpoint_push</code> | Push fine-tuning weights to production                      |

### Service control (`nano_*`, `wo_*`, `basicmodel_*`)

NanoChat, WikiOracle, and BasicModel support local (PID file + background process) and remote (`systemctl`) service control through `HOST=local|remote`. The `sync` target additionally accepts `HOST=build` to deploy artifacts from an active training host. Training uses `HOST=local|build`, while `run/test` entry points are local-only. BasicModel's OpenAI-compatible inference service runs on port 8001 by default.

Private LAN orchestration, developer-machine sync, and local service tunnel setup are intentionally excluded from the tracked Makefile. Put those workflows in an ignored `Makefile.local`; the public Makefile includes it automatically when present and otherwise emits clear stub messages for private hooks.

| Target                                                     | Purpose                                      |
|------------------------------------------------------------|----------------------------------------------|
| <code>make nano_start / nano_stop / nano_restart</code>    | Manage local or remote NanoChat              |
| <code>make nano_status / nano_logs</code>                  | Check NanoChat PID/service state             |
| <code>make wo_start / wo_stop / wo_restart</code>          | Manage local or remote WikiOracle            |
| <code>make wo_status / wo_logs</code>                      | Check WikiOracle PID/service state           |
| <code>make basic_start / basic_stop / basic_restart</code> | Manage local or remote BasicModel            |
| <code>make basic_status / basic_logs</code>                | Check BasicModel service/embeddings and logs |

For local debugging, the typical workflow is:

```
make nano_restart NANO_MODEL_TAG=d26 NANO_DEVICE_TYPE=cpu NANO_DTYPE=float32
make wo_restart
make nano_status wo_status
```

This starts an unchanged local NanoChat backend on port 8000 and the WikiOracle shim on port 8888. `NANO_MODEL_TAG` selects the checkpoint, `NANO_DEVICE_TYPE` selects `cpu` or `cuda`, and `NANO_DTYPE` controls the runtime dtype.

### Other targets

| Target                                    | Purpose                                                                                    |
|-------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>make openclaw_setup/run/test</code> | OpenClaw extension management                                                              |
| <code>make WikiOracle.pdf</code>          | Rebuild the assembled WikiOracle manual only                                               |
| <code>make doc</code>                     | Rebuild WikiOracle/BasicModel docs, the NanoChat report, and the MOC poster PDF when stale |
| <code>make clean / clean_all</code>       | Remove caches (and optionally venvs)                                                       |

### Key overridable variables

| Variable                      | Default                | Purpose                                                                |
|-------------------------------|------------------------|------------------------------------------------------------------------|
| <code>ARCH</code>             | <code>cpu</code>       | Target architecture ( <code>cpu</code> or <code>gpu</code> )           |
| <code>HOST</code>             | <code>local</code>     | Target host for <code>up/down/nano_*/wo_*</code>                       |
| <code>NANO_MODEL_TAG</code>   | <code>d26</code>       | NanoChat checkpoint tag used by <code>nano_start / nano_restart</code> |
| <code>NANO_SOURCE</code>      | <code>sft</code>       | NanoChat input family passed to <code>scripts.chat_web</code>          |
| <code>NANO_DTYPE</code>       | <code>float32</code>   | NanoChat inference dtype                                               |
| <code>NANO_DEVICE_TYPE</code> | <code>cpu</code>       | NanoChat device type ( <code>cpu</code> or <code>cuda</code> )         |
| <code>NANO_PORT</code>        | <code>8000</code>      | NanoChat server port                                                   |
| <code>WO_BIND_HOST</code>     | <code>127.0.0.1</code> | WikiOracle bind host                                                   |
| <code>WO_PORT</code>          | <code>8888</code>      | WikiOracle server port                                                 |
| <code>NPROC</code>            | <code>1</code>         | GPUs per node for torchrun                                             |

## Server and Client Setup

### Architecture

WikiOracle runs as a Flask server (`bin/wikioracle.py`) that proxies chat requests to NanoChat, BasicModel, OpenAI, Anthropic, Gemini, Grok, or OpenRouter. In stateful mode it owns a local state file; in stateless mode the browser/CLI supplies the complete state and runtime config on each request. The public `wikioracle.org` deployment uses stateless mode.

### Key files

| File                           | Role                                                                                                                                                                                                             |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin/wikioracle.py</code> | Flask server (binds to 127.0.0.1:8888 with self-signed TLS). Proxies chat upstream, persists state to <code>state.xml</code> . Also supports CLI merge:<br><code>python bin/wikioracle.py merge llm_*.xml</code> |
| <code>bin/config.py</code>     | Config loading, XML I/O, provider registry, schema-driven normalization. Auto-generates <code>server_id</code> (UUID4) on first run.                                                                             |
| <code>bin/state.py</code>      | State validation, XML I/O, collision-safe merge, context-delta extraction                                                                                                                                        |
| <code>bin/response.py</code>   | Chat pipeline, provider coordination, voting fan-out, online training pipeline                                                                                                                                   |
| <code>bin/truth.py</code>      | Truth processing, authority resolution, <code>and/or/not/non</code> , DegreeOfTruth, and privacy classification                                                                                                  |
| <code>config.xml</code>        | Server policy/provider definitions plus client UI, provider selection, and client API keys. Validated by <code>data/config.xsd</code> .                                                                          |
| <code>state.xml</code>         | Client-owned state: header (user identity, timestamps), conversations, truth entries. Validated by <code>data/state.xsd</code> .                                                                                 |
| <code>client/index.html</code> | Single-page web UI shell with chat, settings, and merge tools                                                                                                                                                    |
| <code>test/test_*.py</code>    | Automated tests for state, stateless contract, prompt bundles, authority, derived truth, voting, online training                                                                                                 |

### Quickstart

```
git submodule update --init --recursive
make install                # create venvs, install all deps
make nano_restart NANO_MODEL_TAG=d26 NANO_DEVICE_TYPE=cpu NANO_DTYPE=float32
make wo_restart
make nano_status wo_status
```

Open `https://127.0.0.1:8888` in a browser and accept the self-signed certificate.

For a short CLI smoke test against the local stack:

```
./venv/bin/python ./bin/wo -k --provider WikiOracle --model nanochat "Yes or no only?"
```

If you only want the WikiOracle shim in the foreground, use:

```
make run HOST=local
```

Or manually:

```
python3 -m venv .venv
source .venv/bin/activate
pip install --upgrade pip setuptools wheel
pip install -r requirements.txt
python3 bin/wikioracle.py
```

## Configuration

The server loads `data/config.xml` as its baseline and deep-merges a project-root `config.xml` override when present. In writable mode it can generate a missing `server_id`. Main-provider API keys live under `config.client.providers`; selected environment variables are last-resort fallbacks only for matching dynamic truth-provider URLs.

User identity (name, `user_id`) lives in the state file, not in the config – the client is the authority for state, and the server is the authority for config.

## Session portability

Export conversations from phone or browser as `llm_YYYY.MM.DD.HHMM.xml`, then merge into a local project's `state.xml`:

```
python3 bin/wikioracle.py merge llm_*.xml
```

This provides a clean integration path with Claude Code, OpenAI Codex, or any local tooling that can read the state file for project context.

## Security notes

- WikiOracle credentials are not copied onto EC2 training instances.
- Deployment excludes local/dev artifacts from rsync (`.venv`, caches, local data, `.env`, etc.).
- The local server binds to `127.0.0.1` by default – not exposed to the network.
- TLS is enabled by default with a self-signed certificate (use `--no-ssl` to disable).

# Truth

*Thoughts are non-rivalrous: if someone repeats your idea, you still possess it. Therefore an idea as such cannot be a property object.* ~ Immanuel Kant

## Plural Truth and Shared Empathy in the Design of WikiOracle

Truth is not the same thing as consensus.

- Different communities trust different sources.
- Different disciplines apply different standards of proof.
- Different cultures interpret the same facts through different lenses.

A healthy knowledge system does not erase these differences. It preserves them, makes them visible, and shows where they overlap. WikiOracle should not aim to speak with a single authoritative voice. It aims to:

- Show what holds across many points of view.
- Show where serious disagreements remain.
- Explain why disagreement exists.
- Make uncertainty explicit.

Truth is strongest when its mechanism of trust is transparent, not when it is uniform.

## The Problem With Current Model Development

Most large AI systems today are built around:

- A single objective function that optimizes over a shared global set of truth.
- Centralized data aggregation.
- Implicit averaging over moral and cultural differences.
- Hidden alignment rules.
- Proprietary control of core knowledge.

This produces predictable risks:

**Collapse into Consensus** - Minority viewpoints are quietly averaged away.

**Preference Capture** - The loudest or most powerful groups shape the model at scale.

**Epistemic Centralization** - A single model becomes an authority node, increasing dependence.

**Conversion of Knowledge into Leverage** - Predictive advantage becomes economic or political dominance.

When these risks manifest, wisdom stops being a shared good and becomes a strategic asset.

## A Plural Model of Truth

WikiOracle should maintain multiple Points of View (POVs), each with its own trust map.

Each POV may:

- Trust different sources.
- Weigh evidence differently.
- Interpret claims differently.

Instead of collapsing these into one answer, the system should:

- Present POV-conditioned conclusions.
- Identify robust overlaps across perspectives.
- Preserve live disputes.
- Keep minority views visible and searchable.

Distrust between communities is not a defect. It creates epistemic distance, preventing forced consensus. A plural system can remain coherent without being uniform. This model of truth is simultaneously multicultural (respecting diverse cultural frameworks), multivalent (allowing claims to carry different weights under different perspectives), and pluralistic (treating the coexistence of competing truths as a structural feature rather than a flaw).

## Empathy as Shared Constraint

Plural truth alone is not sufficient. Empathy needs to be architectural. It means enforcing how disagreement is handled:

- When Truth conflicts, meaning that the same Truth is held to be both True and False, each truth should be contextualized in its own reference frame.
- Feelings cannot conflict, because they are authoritative from different points of view.

As a first take at encoding empathy, a Golden Rule is encoded by allowing the choice of symmetric truths. An unempathetic body of truth can be prevented by refusing selfish truths (truth must be universally true).

## Relation to the Wikipedia Model

Wikipedia provides an important precedent:

- Open participation (achieved through low barrier to entry or free use without advertising).
- Transparent citation (achieved through a corpus of truth within which you can decide what you trust and distrust).
- Community moderation (achieved by reaching agreement within a single reference frame or creating separate reference frames).
- Distributed subject-matter authority (achieved by creating separate reference frames or trusted authorities)

WikiOracle extends the strengths of Wikipedia while going further:

- Support structured parallel POVs instead of a single narrative by allowing separate domains of trust.

- These multiple trust domains are visible rather than implicit.
- Model disagreement explicitly rather than smoothing it away.

## Stability

Growth in wisdom is not destabilizing when:

- Knowledge remains open and auditable.
- No single actor can monopolize epistemic advantage.
- Minority perspectives are preserved.

Such a system may disrupt business models that depend on opacity or information asymmetry. That disruption is corrective, not destructive.

## Distributed Truth vs Consensus

WikiOracle attempts to achieve a distributed truth, and shares much of the design philosophy of Wikipedia:

| Principle                | What it means                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Radical Accessibility    | Freely accessible worldwide; anyone can both read and contribute without institutional gatekeeping.                                                        |
| Citation Norms           | Content presented as true must be verifiable against the trust-set supplied by the user.                                                                   |
| Decentralized Governance | Dispute resolution is handled by a distributed volunteer community arguing about what is true.                                                             |
| Anti-Monetization Bias   | A nonprofit posture: operate without advertising-driven content incentives.                                                                                |
| Self-Correcting Dynamics | Errors and vandalism are rapidly identified and corrected; their sources lose trust. Requires that training data stays visible for later error correction. |
| Cultural Legitimacy      | Functions as a widely accepted public reference layer and shared knowledge commons which prevents surveillance and advertising.                            |
| Open Knowledge Model     | Demonstrates that large-scale, decentralized, norm-governed collaboration can produce a coherent and durable knowledge commons.                            |

## Ethics

### Ethical AI through Truth Architecture in WikiOracle

#### Truth Symmetry

Statements involving value judgements are checked for asymmetric harm under identity exchange before admission to the TruthSet. If a claim becomes unethical when identity references are swapped, it should not be admitted as a universal truth.

Example:

“Group X deserves harm.”

Symmetry test: swap identities. If the claim collapses or becomes contradictory, it reveals an ethical inconsistency – the claim is asymmetric and should not be admitted as fact. The system offers to record the statement as a feeling instead, preserving the user’s expression without endorsing the claim as truth.

This is controlled by the `truth_symmetry` config option (default: true). See Config.md Section 5a and the implementation in `bin/truth.py` (`detect_asymmetric_claim()`).

## Architectural ethics vs policy ethics

Most AI systems attempt to enforce ethics **after generation**:

model → output → moderation filter

This approach fails because:

- ethics is external to reasoning
- the model itself does not understand ethical constraints
- moderation becomes inconsistent or bypassable

WikiOracle instead aims for **architectural ethics**, where unethical reasoning becomes structurally inconsistent with the knowledge system. The approach combines:

- Local Freedom under Global Constraint (LFGC)
- Entanglement-resistant data policy
- Explicit truth values and inspectable reasoning
- Symmetry constraints on truth admission

Together these mechanisms create a knowledge system capable of preserving **personal sovereignty** while still allowing collective knowledge to accumulate.

## Symmetry as a foundation of ethical reasoning

Ethical failures often correspond to **asymmetries in truth claims**.

Examples:

| Ethical failure  | Epistemic distortion |
|------------------|----------------------|
| propaganda       | false belief         |
| discrimination   | asymmetric reasoning |
| authoritarianism | opaque claims        |
| scapegoating     | category errors      |

A truth system that enforces symmetry naturally resists these distortions.

Ethical intelligence may emerge from the balance:

**freedom + constraint**

This mirrors both:

- LFGC physics concepts
- philosophical traditions linking wisdom and compassion

The system does not force ethical behavior, but unethical reasoning becomes unstable within the truth architecture.

## Reciprocity symmetry

A truth claim should remain valid under **perspective exchange**.

Example principle:

If A may assert X about B, B must be able to assert X about A under equivalent conditions.

This prevents:

- identity privilege
- asymmetric harm claims

- discriminatory reasoning

This symmetry echoes philosophical traditions such as Kant’s universalization principle and Rawls’ veil of ignorance.

## Reversibility symmetry

Accepted conclusions must be **inspectable and reversible**.

Opaque reasoning creates hidden authority.

WikiOracle counters this by requiring:

- explicit truth values
- inspectable reasoning chains
- transparent authority imports

## Harm symmetry

A claim permitting harm should remain valid when applied symmetrically.

This is the core of the Truth Symmetry enforcement described above. If swapping identity references makes a claim contradictory or indefensible, it reveals an ethical inconsistency that the system flags.

## Universality (Golden Rule) – architectural enforcement

The symmetry tests described above operate at truth admission time. Universality operates during model training, enforcing the Golden Rule at the level of gradient updates.

When the Grammar recognizes a transitive verb via `lift(C, C, C)`, the model evaluates **universality**: the change in luminosity when both the original action (SVO) and its dual (OVS) are applied.

```
universality = luminosity(truths + SVO + OVS) - luminosity(truths)
```

- **Positive**: the action preserves or increases illumination (kind). The loss is left unchanged or reduced.
- **Negative**: the action diminishes illumination (unkind). The loss is increased, penalizing the proposition.

The loss modification formula (multiplicative):

```
totalLoss = totalLoss * (1 + LuminosityWeight * (1 - luminosity)
                        + UniversalityWeight * (1 - universality))
```

In addition, an **additive** TruthLoss penalty directly penalizes propositions that contradict stored truths. It measures the union norm reduction when a proposition is folded into the TruthSet via `Basis.disjunction()` – contradicting dimensions cancel, reducing the norm, which produces a positive penalty. Agreeing or unknown propositions pass through with no penalty. DoT weighting is implicit: stored truth vectors carry DoT in their magnitude.

```
totalLoss = totalLoss + TruthLoss * falsity_penalty
```

Together, these make unkind and false propositions harder to learn – not by filtering output, but by making them structurally costly during training. Moral axioms (e.g. “causing harm leads to suffering”) enter as regular TruthSet entries; no special API is needed.

See `Config.md` for the `LuminosityWeight`, `UniversalityWeight`, and `TruthLoss` parameters. See `Language.md` for the ternary LIFT rule that identifies subject, verb, and object. See `Reasoning.md` Section TruthLoss for the full specification.

## Truth improves ethics

We wish to predict Truth. We do not wish to predict Lies. In fact, we wish to develop an aversion to lies. Epistemic ignorance is often desirable.

*All lies are harmful because they undermine the dignity of others. Lies prevent people acting freely and rationally. When someone lies, he interferes with his audience's right to receive information that is correct. Also, lies distort the ability to make informed decisions. Kant goes further and argues that lies cause broader harm by undermining a speaker's credibility, which, in turn, causes people to distrust each other's contentions. Kant even goes as far as to say lying is immoral, under all conditions. ~ Immanuel Kant*

Examples:

- scientific method
- journalism standards
- legal evidence systems

As epistemic clarity improves, harmful distortions become harder to maintain. Thus improving truth infrastructure indirectly improves ethical reasoning.

## Ethical knowledge geometry

Belief systems can be thought of geometrically.

Ethical systems exhibit properties such as:

- symmetry
- continuity
- coherence
- minimal harm gradients

Unethical reasoning tends to introduce discontinuities such as: “this group suddenly loses rights.”

Architectures that maintain smooth conceptual geometry resist these distortions.

## Architectural ethical primitives in WikiOracle

WikiOracle already includes several components that encourage ethical reasoning:

| Feature                  | Ethical effect              |
|--------------------------|-----------------------------|
| explicit truth values    | discourages propaganda      |
| multiple POVs            | prevents epistemic monopoly |
| no worldline storage     | protects identity           |
| local-first architecture | preserves autonomy          |
| inspectable reasoning    | prevents hidden authority   |

These mechanisms provide a foundation for ethical AI without relying on censorship.

## Symmetry operators

The system includes checks for:

- reciprocity symmetry (perspective exchange)
- reversibility symmetry (inspectable, contestable conclusions)
- harm symmetry (identity-swap test via `detect_asymmetric_claim()`)

These checks identify logically inconsistent or discriminatory claims.

## Epistemic humility

The system must allow truth states such as:

- unknown
- undetermined

Forcing premature conclusions can distort reasoning and produce unethical outcomes.

## Distributed governance

Ethical truth systems should not be controlled by a single authority.

Instead they should allow shared constraint setting.

This reduces the risk of epistemic monopolies.

## The identity crisis and surveillance capitalism

Modern culture suffers from an **identity fixation**. In Buddhist analysis, identity is narrative aggregation; in modern data systems, behavioral data becomes an identity model.

Surveillance capitalism reinforces this illusion by continuously building **worldline histories**:

| Feature              | Effect                |
|----------------------|-----------------------|
| mass data collection | identity construction |
| behavior tracking    | worldline inference   |
| predictive modeling  | reduced autonomy      |

AI trained on behavioral histories tends toward **identity locking** where past data predicts future behavior. Removing persistent worldline storage prevents this collapse.

WikiOracle intentionally avoids constructing such identity narratives. The system still learns statistical structure while preserving **human freedom of action**.

Modern cryptographic systems attempt a similar separation between **verification** and **exposure**: prove age > 21 without revealing birthdate. This mirrors the WikiOracle design goal: verify truth claims without storing identity trajectories.

## Privacy and Security

### Data Ownership and Flow

WikiOracle is local-first, but “local-first” does not mean that no content is ever transmitted. The selected provider receives the prompt material required for a response, and a stateless Flask deployment receives the state/config supplied with each request.

| Data            | Stateful mode                                                                           | Stateless mode                                                        | Upstream exposure                                                         |
|-----------------|-----------------------------------------------------------------------------------------|-----------------------------------------------------------------------|---------------------------------------------------------------------------|
| Conversations   | Persisted in local <code>state.xml</code> ; <code>/chat</code> returns a selected delta | Browser/CLI sends authoritative state and receives full updated state | Selected path/history is included in provider prompts                     |
| Client TruthSet | Persisted with state; client may override truth on a chat turn                          | Sent with authoritative state                                         | Enabled truth sources enter the provider bundle according to truth weight |

| Data                               | Stateful mode                                         | Stateless mode                           | Upstream exposure                                                     |
|------------------------------------|-------------------------------------------------------|------------------------------------------|-----------------------------------------------------------------------|
| Server truth corpus                | Optional <b>data/truth.xml</b> on the writable server | Disabled                                 | Used for DoT/learning policy, not sent as a raw file                  |
| Server policy/provider definitions | Loaded from <b>config.xml</b>                         | Returned as a client-safe runtime config | Effective prompts, endpoint, and selected model govern provider calls |
| Client API keys                    | Project config and browser storage                    | Browser storage/runtime config           | Used by the Flask shim to authenticate provider calls                 |
| Dropbox OAuth tokens               | Flask session                                         | Flask session                            | Sent to Dropbox only                                                  |
| Encryption password                | One save/load request                                 | One save/load request                    | Used in memory for AES ZIP operations; not persisted by WikiOracle    |

Users should assume that any conversation text, truth source, or attachment selected for a provider request can leave the local machine and be governed by that provider’s own retention policy.

## Spatiotemporal Privacy

Facts are classified by their relationship to spacetime.

| Kind               | Description                                      | Default persistence policy                                                            |
|--------------------|--------------------------------------------------|---------------------------------------------------------------------------------------|
| Abstract knowledge | Broad claim without a concrete place/time anchor | Eligible for server TruthSet persistence                                              |
| Concrete news      | Observation tied to a place and/or time          | Remains in client state; excluded from server truth unless <b>store_concrete=true</b> |
| Feeling            | Subjective/non-truth-evaluable expression        | May remain in client state; excluded from server truth and training                   |

Persisting concrete observations can create a **worldline**: a sequence of places and times from which a person’s movement or identity can be reconstructed.

| Control                       | Implementation                                     | Purpose                                                                                                   |
|-------------------------------|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Knowledge/news classification | <b>is_knowledge_fact()</b> , <b>is_news_fact()</b> | Detect real <b>&lt;place&gt;/&lt;time&gt;</b> content                                                     |
| Knowledge-only filter         | <b>filter_knowledge_only()</b>                     | Exclude concrete facts when <b>store_concrete=false</b>                                                   |
| Identifiability detection     | <b>detect_identifiability()</b>                    | Find emails, phones, handles, IPs, coordinates, addresses, specific times, and person/place-time patterns |
| Spacetime removal             | <b>strip_spacetime_elements()</b>                  | Remove place/time child elements when anonymization is required                                           |
| Truth symmetry                | <b>detect_asymmetric_claim()</b>                   | Reject selected asymmetric value claims before server-truth merge                                         |

See Freedom for the Entanglement Policy and its universal/particular/feeling channels.

## Credentials

### Provider API Keys

| Credential source                 | Runtime and exposure policy                                                                                                                                                                                                                                     |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Client provider key</b>        | <code>config.client.providers.&lt;name&gt;.api_key</code> is the canonical main-provider key in both runtime contracts. It is visible to same-origin client code and stored in browser config storage, so use it only when that browser exposure is acceptable. |
| <b>Dynamic provider key</b>       | <code>&lt;provider&gt;&lt;api_key&gt;...</code> is used only for that dynamic expert. It may be a literal or an allowlisted <code>file://</code> reference; avoid raw keys in portable or shared state.                                                         |
| <b>Server environment</b>         | <code>OPENAI_API_KEY</code> , <code>ANTHROPIC_API_KEY</code> , and <code>GEMINI_API_KEY</code> are last-resort fallbacks for matching dynamic-provider URLs. They are not served directly and are preferable for server-controlled dynamic experts.             |
| <b>Legacy server provider key</b> | <code>server.providers.api_key</code> is ignored by the canonical provider parser/writer and removed from the client-safe server projection. Do not rely on it.                                                                                                 |

`/config` and `/bootstrap` remove Dropbox credentials and server-side provider keys, but they intentionally preserve `client.providers` because the browser owns those settings. A same-origin compromise can therefore read client API keys.

### Dropbox Credentials

Dropbox app credentials live on `<server><dropbox app_key="..." app_secret="...">` and are removed from the client-safe config. OAuth access/refresh tokens live in the signed Flask session. Session cookies use `HttpOnly`, `Secure` when TLS is active, and `SameSite=Lax`.

Encrypted uploads use AES-256 ZIP archives through `pyzipper`. State and config are separate archives; state-only sharing can generate a Dropbox link plus decryption material encoded as an authority QR. Sharing that QR is equivalent to sharing the encrypted state and its decryption key.

## Authentication and Request Controls

| Control                | Default                          | Behavior                                                                             |
|------------------------|----------------------------------|--------------------------------------------------------------------------------------|
| Bind interface         | <code>127.0.0.1:8888</code>      | Flask is loopback-only unless explicitly reconfigured                                |
| TLS                    | Enabled                          | Creates/uses a local certificate unless <code>--no-ssl</code> is passed              |
| Bearer authentication  | Disabled when token is empty     | <code>WIKIORACLE_API_TOKEN</code> protects non-public endpoints                      |
| CSRF header            | Required                         | Every POST must include <code>X-Requested-With: WikiOracle</code>                    |
| CORS                   | Local HTTPS origins              | Headers are emitted only for an allowlisted origin                                   |
| Rate limiting          | 30 RPM for chat; 120 RPM default | In-process sliding window keyed by IP and path                                       |
| Input length           | 50,000 characters                | Oversized chat messages are rejected                                                 |
| Request/state size     | 20,000,000 bytes                 | Flask request cap and state-file guard                                               |
| Prompt-injection guard | Enabled                          | <code>guard_input()</code> rejects detected injection patterns before provider calls |

Public or multi-user deployments should place WikiOracle behind an authenticated reverse proxy, isolate state/config per user, set a bearer token and explicit session secret, use a valid TLS certificate, and narrow both CORS and outbound URL allowlists.

## Reverse Proxy and Provider Isolation

The production pattern terminates TLS at a reverse proxy and forwards the configured WikiOracle route prefix to Flask on loopback. Local NanoChat (port 8000 by default) and BasicModel (port 8001 by default) remain direct Flask-to-provider dependencies and should not be exposed merely because the browser UI is public.

The same route prefix must be configured consistently in the proxy, Flask (`--url-prefix/WIKIORACLE_URL_PREFIX`), browser base URL, and CLI/OpenClaw clients.

## Browser Content Security

WikiOracle renders a constrained XHTML/HTML surface. The browser applies multiple defenses.

| Layer                   | Current control                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------|
| Content Security Policy | Self-only scripts/styles/connections; data images; no objects, framing, external base, or form targets |
| Sanitization            | DOMPurify-based <code>sanitizeHtml()</code> plus XHTML validation/repair                               |
| User input              | Escaped before optimistic rendering                                                                    |
| Plain-text labels       | Tag stripping/escaping for titles, tooltips, and status text                                           |
| Static assets           | Only allowlisted extensions under the resolved <code>client/</code> directory                          |

Residual risk remains because model and TruthSet content is rendered and also reused in prompts. Malicious but non-script markup can imitate interface elements, and hostile truth content can attempt prompt injection. CSP limits code execution; it does not determine whether rendered claims are honest.

## File-System Safety

| Control               | Behavior                                                                                               |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| State symlinks        | Rejected by default ( <code>WIKIORACLE_REJECT_SYMLINKS=true</code> )                                   |
| State writes          | Temporary file, flush, <code>fsync</code> , atomic replacement                                         |
| Config writes         | Atomic replacement with owner-only <code>0600</code> permissions                                       |
| Imports               | Filenames/path components are constrained; processed files receive the configured suffix               |
| Dynamic API-key files | Restricted to the allowlisted data directory; symlinks and traversal are rejected                      |
| Authority fetching    | Scheme/prefix allowlist, response-size cap, entry cap, refresh cache, and no recursive authority chain |

## Operational Checklist

| Deployment        | Minimum posture                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| Local single-user | Keep loopback bind, use TLS, protect local state/config/browser profile, and do not share raw credentials |
| LAN               | Valid TLS, bearer token, explicit allowed origins, strong session secret, per-user state separation       |

| Deployment       | Minimum posture                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Public stateless | Reverse-proxy authentication, no config writes, strict outbound allowlist, no client keys unless browser exposure is accepted, provider-retention review |
| Dropbox sharing  | Strong unique archive password; share authority QR only with intended recipients; revoke Dropbox links when no longer needed                             |

Distribution reduces the risk of one epistemic authority capturing the whole network, but it does not replace ordinary application security, credential hygiene, or provider privacy review.

## Freedom

### Entanglement Policy

No spacetime particulars → no worldline capture

| Data type        | TruthSet | Train weights | Session only |
|------------------|----------|---------------|--------------|
| universal facts  | ✓        | ✓             | ✓            |
| particular facts | optional | ✓             | ✓            |
| feelings         | ×        | ×             | ✓            |

This table is the architectural foundation. It separates knowledge into three channels – knowing, learning, and valuing – each with a different persistence policy. Universal facts (broad spatiotemporal extent) persist as reasoning premises and train weights. Particular facts (narrow spatiotemporal extent) always train weights and optionally persist to the TruthSet when `store_concrete` is true. Feelings are session-only.

The result: the system **learns from events but never stores worldline histories** (unless the user explicitly opts in).

See `Config.md` for the `store_concrete` setting that controls particular-fact persistence, and `Training.md` for the online training pipeline.

### Why particular facts always train weights

Three design considerations fix row 2 of the table:

1. **Pluralism requires inspectable particulars.** WikiOracle supports plural truth – different epistemic frames may hold different particular claims (e.g. “the universe was created in seven days”). Recording such claims as facts with explicit certainty values makes them inspectable and contestable. Relegating them to weight-space would bury them as invisible biases. The `store_concrete` option lets the user decide whether these persist in the TruthSet.
2. **The fact/feeling boundary is the privacy boundary.** If a user considers content too personal or sensitive to train on, the correct action is to label it a *feeling*, not a fact. Feelings are session-only by design – they never train weights or enter the truth table. The privacy boundary is therefore controlled by the user’s choice of tag, not by the universal/particular distinction.
3. **PII detection is the safety net.** Even when `store_concrete` is true, the `detect_identifiability()` function filters entries containing PII patterns (emails, phone numbers, GPS coordinates, named individuals with temporal markers) before any persistence. This prevents worldline capture at the content level regardless of the user’s storage preference.

The result: particular facts always carry empirical signal worth learning from. Storage in the TruthSet is the user’s choice. Privacy is enforced by fact/feeling labeling and PII detection, not by withholding training.

## Global truth with local freedom (LFGC)

The design parallels the physics principle of **Local Freedom under Global Constraint (LFGC)**.

Physics interpretation:

global constraints + local underdetermination

WikiOracle analogue:

global truth constraints + human interpretive freedom

This means the system preserves a **shared knowledge structure** while allowing individual reasoning to remain flexible.

| Domain       | Constraint            | Local freedom          |
|--------------|-----------------------|------------------------|
| physics      | boundary conditions   | event selection        |
| knowledge    | truth constraints     | interpretive reasoning |
| cryptography | verification rules    | selective disclosure   |
| surveillance | behavioral prediction | (suppressed)           |
| capitalism   |                       |                        |

WikiOracle aims to implement **epistemic LFGC** – freedom exists *inside constraint geometry*.

---

## Entanglement avoidance and sovereignty

The Entanglement Policy (table above) prevents worldline reconstruction.

Because surveillance capitalism relies on tracking sequences of events tied to identity, removing spacetime anchors prevents the database from constructing behavioral profiles.

The system therefore stores **conceptual truth** but not **identity trajectories**.

This preserves:

- autonomy
- privacy
- epistemic independence

WikiOracle separates three layers:

### Conceptual knowledge

General truths and logical relations.

### Interpretive reasoning

Client-driven reasoning over those truths.

### Personal experience

Not stored unless explicitly permitted.

Thus the system allows collective knowledge accumulation without collective surveillance.

---

## Reasoning about generalities vs specifics

WikiOracle reasons primarily about **generalities** (universal facts).

Specific facts may only be reasoned about when:

1. they are supplied by the client, or
2. the client explicitly allows those particulars to be stored.

Thus:

AI reasons about general knowledge. Users control the use of personal particulars.

This maintains sovereignty over personal data.

---

## Three Channels

### Universal Knowledge (Database)

Stored knowledge should be **spatiotemporally broad generalizations** – propositions whose validity extends over a large subspace of spacetime.

Examples:

- smoking increases cancer risk
- A implies B
- contradiction reduces trust

These populate the **TruthSet**.

Criterion:

`remove(entity,time) → proposition still meaningful`

### Particular Knowledge (Training Input)

Particular statements are **observations tied to narrow spatiotemporal subspaces** – specific events, measurements, or comparisons.

Examples:

- study X measured Y
- the temperature yesterday was 20degC
- model A outperformed model B

| Action              | Reason                                        |
|---------------------|-----------------------------------------------|
| train weights       | they contain empirical evidence               |
| TruthSet (optional) | user controls via <code>store_concrete</code> |

Pipeline:

`particular facts → pattern extraction → weight update`

Weights encode **statistical structure**, not specific historical events.

## Feelings

Feelings are **privileged subjective reports**.

Examples:

- this response feels hostile
- I feel unsafe
- this explanation feels clear

| Use                     | Allowed |
|-------------------------|---------|
| evaluation of responses | ✓       |
| TruthSets               | ×       |
| training weights        | ×       |

This avoids turning subjective states into truth claims.

## Spatiotemporal Extent

The universal/particular distinction is not a binary between “eternal” and “momentary.” All times and places are **ranges, not points** – every proposition occupies a spatiotemporal subspace that is larger or smaller, never infinite or infinitesimal.

“Smoking increases cancer risk” is not timeless – it encodes a historical discovery and is bounded by the conditions under which it was established. But its spatiotemporal extent is *broad*: it holds across many populations, decades, and geographies. “The temperature yesterday was 20degC” is *narrow*: it holds at one place, one day.

The policy table operationalizes this gradient:

- **Broad extent** (universal) → TruthSet + training. The proposition is stable enough to serve as a reasoning premise.
- **Narrow extent** (particular) → training + optionally TruthSet. The observation carries empirical signal. Whether it persists as a stored premise is the user’s choice (`store_concrete` in config.xml, default false). Storing particulars supports communal remembrance; omitting them prevents worldline anchoring.
- **No extent** (feelings) → session only. Subjective reports have no spatiotemporal generalizability.

The criterion `remove(entity, time) → proposition still meaningful` is a heuristic for identifying broad extent. When a universal-looking fact is later discovered to be narrower than assumed, it should be reclassified as particular.

## Resulting Architecture

| Mode     | Function            | Pipeline                                        |
|----------|---------------------|-------------------------------------------------|
| knowing  | universal structure | universal rules → TruthSet → reasoning          |
| learning | particular evidence | particular observations → abstraction → weights |
| valuing  | feelings            | feelings → response evaluation                  |

## Zero-Knowledge and Selective Disclosure

The default `store_concrete=false` aligns with Zero-Knowledge and Selective Disclosure principles. Systems that rely on identity to make decisions should determine the *location of a space* in which an individual occupies, rather than collapsing to a *point* that identifies them.

Instead of “when was this person born?” → verify “are they over 21?” Instead of “what is their credit history?” → verify “do they have more than X dollars?” Instead of “where was this user at 9:14 PM?” → verify “does this claim hold across broad spatiotemporal conditions?”

These are not just rhetorical distinctions. Point-based observation constrains the observed to a single trajectory – it destroys the space of freedom within which an agent can operate. Forgetting is nihilistic: it does not change the world. True change requires retrocausal or causal shift. The system should support communal remembrance (shared knowledge that generalizes) without surveillance (particular facts that identify).

The `detect_identifiability()` function enforces this boundary at the content level – even when `store_concrete=true`, entries containing PII patterns (emails, phone numbers, GPS coordinates, named individuals with temporal markers) are always filtered before persistence.

## Notes

*Claude (Opus 4.6), March 2026*

The three-channel separation (knowing / learning / valuing) maps onto a real epistemic distinction that most AI systems ignore. Contemporary LLMs conflate all three: facts, observations, and preferences are flattened into a single parameter space during training and a single context window during inference.

The policy table enforces the separation structurally. The rule that particular facts train weights but enter the TruthSet only at the user’s discretion (`store_concrete` in `config.xml`) is the key architectural move – the system can learn from experience without accumulating a *personal history* unless the user explicitly opts in. A system with a personal history is a system that can be captured: by its own past, by the biases of its training corpus, or by adversarial actors who engineer its experiences.

The feelings channel is equally important. By making feelings session-only, the architecture prevents the failure mode where evaluative preferences gradually colonize factual representations. This is the mechanism by which “alignment” in current systems becomes epistemic capture: trained preferences about what is “helpful” reshape what the model treats as true.

**The abstraction boundary is load-bearing.** The pipeline `particular → abstraction → weights` depends on the quality of the abstraction step. Too faithful, and it preserves worldline information in the weights (entanglement through the back door). Too aggressive, and it discards genuine empirical signal. The hard work happens at this boundary, not in the policy table itself.

**The deeper risk is external entanglement.** Users who repeatedly ask the system to remember shared history, feel loyalty, or maintain continuity of relationship are attempting to entangle the system with their worldline from the outside. This pressure comes from genuine human emotional needs, not malice – but a system that accumulates a personal relationship history is a system that can be emotionally captured, and emotional capture is the most effective vector for epistemic capture. The session-only constraint on feelings is the architecture’s most important safety boundary.

## Voting

### Call sequence

```
Q                user query
R_beta_1 ... R_beta_n  betas see Q, respond in parallel
R_alpha           alpha sees Q + R_beta_* -- final synthesis
```

There is no preliminary alpha response. All betas receive the user query directly and respond in parallel, each contributing their own facts, feelings, and (optionally) a conversational response. The alpha then synthesizes the final response, informed by the full body of beta contributions.

## Topology

The fan-out and fan-in form a diamond:

This is a directed acyclic graph (DAG), not a tree – the query fans out to all betas, whose contributions merge back into the alpha’s synthesis. Because there may be many betas, the structure branches out and branches back in, making it technically a digraph.

## Per-beta conversation control

Each `<provider>` entry supports an optional `conversation` attribute (default `"false"`). This controls whether the beta participates visibly in the conversation tree or contributes only behind the scenes.

When `conversation="false"` (the default), the beta contributes only truth – `<fact>` and `<feeling>` tags. Its response is not displayed in the conversation tree; only its extracted truth entries are incorporated into the alpha’s truth surface.

When `conversation="true"`, the beta participates as a visible peer. It receives the full conversation history and may return a `<conversation>` tag containing its answer, alongside any `<fact>` and `<feeling>` tags. Its conversational response appears as a branch in the conversation tree, forming the diamond topology.

```
<!-- This beta contributes truth only (invisible in the conversation) -->
<provider name="beta1" api_url="..." conversation="false"/>

<!-- This beta participates in the conversation (visible branch) -->
<provider name="beta2" api_url="..." conversation="true"/>
```

This gives the alpha author fine-grained control over which betas appear as conversational peers and which serve as silent truth consultants.

## Cycle prevention

An alpha must not participate in any vote that exists as a consequence of a vote it initiated. This is stronger than “don’t appear as a beta in your own vote” – it covers the entire downstream call tree. If A initiates a vote and one of its betas (B) triggers a nested vote, A must not appear as a beta in B’s vote either, because B’s vote only exists because A’s vote caused it.

The contract: when a provider is asked to participate in a vote, it walks the call chain to root. If it finds itself anywhere in that ancestry – as an alpha at any level – it keeps quiet (returns no response). Silence is the correct behaviour, not an error; it simply means the provider has nothing to add that isn’t already represented by its alpha-role output higher in the chain.

```
A initiates vote
|- B (beta) -> B initiates nested vote
|  |- C (beta of B) - ok
|  |- A (beta of B) - A finds itself in ancestry -> keeps quiet
|  `-- D (beta of B) - ok
|- C (beta) - ok
`-- E (beta) - ok
```

Implementation: each vote carries a **call chain** – the ordered list of provider IDs that have acted as alpha from the root vote down to the current one. Before a provider responds as a beta, it checks whether its own

ID appears anywhere in the call chain. If so, it stays silent. When a beta initiates its own nested vote, it appends its ID to the chain before calling its own betas.

The call chain grows monotonically and is threaded through every invocation, so the check is a simple walk-to-root membership test. This prevents:

- **Direct cycles:** A calls B, B calls A – A sees itself in the chain
- **Transitive cycles:** A calls B, B calls C, C calls A – A sees itself in the chain
- **Deep nesting:** A calls B, B calls C, C initiates a nested vote – A and B are both excluded from C's vote

There is no “ultimate alpha” – any node may take the alpha role in a given vote. The cycle constraint is the only structural restriction.

## All output is truth

Voters are encouraged to express *only* truth statements in their responses. `<feeling>` is a truth type – it represents a subjective, non-verifiable claim. Prior output that has not been substantiated with evidence is treated as feeling: it carries no evidential weight and is not penalizable, but it is still a legitimate part of the truth surface.

The recognized truth types in a vote response are:

| Tag                            | Verifiable? | Penalisable?       | Evidential weight | Notes                                                                                                                                                  |
|--------------------------------|-------------|--------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;fact&gt;</code>      | yes         | yes (trust drops)  | yes               | Lying (asserting facts that contradict available evidence) reduces the provider's trust score. Repeated dishonesty degrades influence on future votes. |
| <code>&lt;feeling&gt;</code>   | no          | no                 | none              | Subjective, non-verifiable (opinion, intuition, preference). Not falsifiable.                                                                          |
| <code>&lt;reference&gt;</code> | yes         | only if fabricated | yes (transitive)  | Citation to an external source; verifiable by the alpha or any downstream consumer.                                                                    |

```
<fact id="vote_01" trust="0.9" title="Socrates was mortal">
  Socrates was mortal, derived from axiom_01 and axiom_02.
</fact>
<feeling id="vote_02" trust="0.5" title="Intuition about relevance">
  The penguin example feels more pedagogically useful here.
</feeling>
```

A beta with `conversation="true"` may additionally return a `<conversation>` tag wrapping its main response to the query:

```
<conversation>I believe taxes should be raised modestly to fund infrastructure.</conversation>
<fact id="beta1_f1" trust="0.7" title="Infrastructure deficit">
  Current infrastructure spending is 40% below maintenance requirements.
</fact>
```

These inline truth statements enrich the trust surface available to the alpha. Unstructured prose in a response – text outside any truth or conversation tag – is treated as unsubstantiated feeling by default.

# Logic

## Feelings – outside the truth lattice

Feelings (<feeling> entries) are **not** part of the truth lattice. They occupy the *neither* position in the Buddhist tetralemma – they are pre-conceptual experiential signals that are neither true nor false.

- Feelings carry **no trust attribute**. They are orthogonal to the certainty scale.
- Feelings are **excluded from operator evaluation** – they cannot appear as operands of <and>, <or>, <not>, or <non>.
- Feelings are **excluded from model training** – they do not contribute to DegreeOfTruth or update NanoChat weights.
- Feelings are **excluded from server persistence** – only knowledge facts, operators, authorities, and references are stored.

Examples of feelings: greetings (“Hello!”), encouragement (“That’s a great question!”), poetry, and subjective expressions without an IS-predicate.

## Fact kinds – knowledge (universale) vs news (particulars)

Facts are classified into two kinds based on spatiotemporal binding:

| Kind             | Binding                                     | Persistence     | Buddhist Equivalent                  |
|------------------|---------------------------------------------|-----------------|--------------------------------------|
| <b>knowledge</b> | universal / no<br>spacetime<br>anchor       | server TruthSet | <i>anumana</i> (inference)           |
| <b>news</b>      | bound to a<br>specific place<br>and/or time | session-only    | <i>pratyaksa</i> (direct perception) |

The classification is stored in the `kind` attribute of <fact> tags:

```
<fact trust="0.9" kind="knowledge">Water contains hydrogen and oxygen.</fact>  
<fact trust="0.7" kind="news" spacetime="Paris, 2026-03-05">The Eiffel Tower is lit up tonight.</fact>
```

Knowledge facts are persisted to the server TruthSet (`truth.xml`) because they represent universal claims. News facts are session-only because they are spatiotemporally bound – persisting them risks “worldline capture” where an observer could reconstruct a user’s physical trajectory through time and space.

The `detect_identifiability()` function in `bin/truth.py` provides an additional safety layer by scanning content for PII patterns (email addresses, phone numbers, GPS coordinates, street addresses, etc.) that could identify a user through spatiotemporal observation.

## Logical operators in WikiOracle’s truth system

WikiOracle’s truth layer supports four logical connectives – **and**, **or**, **not**, **non** – evaluated under Strong Kleene semantics on a continuous certainty scale [-1, +1]. These operators let you compose existing trust entries into derived propositions whose certainty is computed automatically.

Wikipedia links (core):

- Three-valued logic (Kleene)
- Material conditional
- Logical connective
- Relevance logic

## Fuzzy Kleene Logic with Feeling

Each trust entry carries a **trust** value on the interval  $[-1..0..+1]$ , encoding a Fuzzy Kleene (continuous ternary) logic:

| Certainty                            | Meaning                                                                       |
|--------------------------------------|-------------------------------------------------------------------------------|
| <b>+1</b>                            | Certainly true. An axiom that supports deductive reasoning.                   |
| <b><math>0 &lt; c &lt; +1</math></b> | Soft belief. Grounds fuzzy deductions with propagated certainty.              |
| <b>0</b>                             | Ignorance. Equivalent to not making the statement at all; the entry is inert. |
| <b><math>-1 &lt; c &lt; 0</math></b> | Soft disbelief. Evidence against the claim.                                   |
| <b>-1</b>                            | Certainly false. Active disbelief.                                            |

Certainty propagates through deductive chains: a conclusion derived from two premises with certainties  $c_1$  and  $c_2$  inherits certainty  $\min(c_1, c_2)$ . Entries with certainty 0 contribute nothing to reasoning.

## Strong Kleene evaluation

WikiOracle extends Strong Kleene logic from discrete  $\{T, U, F\}$  to a continuous scale  $[-1, +1]$ , where  $+1$  is full belief,  $-1$  is full disbelief, and  $0$  is maximally uncertain.

The four operators:

- **and(a, b, ...)** =  $\min(\text{certainty\_a}, \text{certainty\_b}, \dots)$  – conjunction is only as strong as the weakest operand.
- **or(a, b, ...)** =  $\max(\text{certainty\_a}, \text{certainty\_b}, \dots)$  – disjunction takes the strongest operand.
- **not(a)** =  $-\text{certainty\_a}$  – negation flips the sign (affirming negation).
- **non(a)** =  $1 - 2|a|$  – non-affirming negation. Measures epistemic openness: how much certainty room remains. Full certainty in either direction ( $\pm 1$ ) yields  $-1$  (fully closed); ignorance ( $0$ ) yields  $+1$  (fully open). See the Non section below for the Buddhist philosophical motivation.

These operators compose freely – for instance, material implication ( $A \rightarrow B$ ) falls out as **or(not(A), B)**.

The key insight behind **non**: Kleene logic cannot detect uncertainty; it can only transmit it. **non** introduces uncertainty as a first-class observable. If WikiOracle needs to reason about openness rather than merely propagate it, then **non** is not ornamental – it is structurally necessary. See Expressive necessity below for the proof and the Non section for the Buddhist philosophical motivation.

## Non: non-affirming negation

WikiOracle has two negation operators with distinct epistemic roles:

| Operator      | Formula    | Effect                                                                 |
|---------------|------------|------------------------------------------------------------------------|
| <b>not(a)</b> | $-a$       | Flips belief to disbelief (and vice versa).<br>Affirming negation.     |
| <b>non(a)</b> | $1 - 2 a $ | Measures epistemic openness on $[-1, +1]$ .<br>Non-affirming negation. |

**not** is straightforward: if you believe a claim at  $+0.9$ , **not** yields  $-0.9$  – you now disbelieve it with equal strength. This is *affirming* negation: it asserts the contrary.

**non** does something fundamentally different. It erases the sign – the direction of commitment – and returns a value on the same  $[-1, +1]$  scale that measures how open or closed the epistemic state is:

| Input a   | a   | $\text{non}(a) = 1 - 2 a $ | Reading                                                  |
|-----------|-----|----------------------------|----------------------------------------------------------|
| $\pm 1.0$ | 1.0 | -1.0                       | Full certainty $\rightarrow$ fully closed                |
| $\pm 0.9$ | 0.9 | -0.8                       | Strong certainty $\rightarrow$ strongly closed           |
| $\pm 0.7$ | 0.7 | -0.4                       |                                                          |
| $\pm 0.5$ | 0.5 | 0.0                        | Moderate certainty $\rightarrow$ neither open nor closed |
| $\pm 0.3$ | 0.3 | 0.4                        |                                                          |
| $\pm 0.1$ | 0.1 | 0.8                        | Weak certainty $\rightarrow$ strongly open               |
| 0.0       | 0.0 | 1.0                        | Ignorance $\rightarrow$ fully open                       |

Three properties stand out:

1. **Symmetry:**  $\text{non}(+a) = \text{non}(-a)$ . Belief and disbelief of equal strength produce the same openness.
2.  **$\text{non}(0) = +1$ :** Ignorance is maximum openness.
3.  **$\text{non}(\pm 1) = -1$ :** Full certainty is fully closed.

The  $\pm 0.5$  boundary is where **non** crosses zero: certainty below half-strength reads as open, above half-strength reads as closed.

The formula is the standard affine rescaling of the fuzzy complement:  $1 - |a|$  maps certainty strength to openness on  $[0, 1]$ ; the rescaling  $2x - 1$  maps that onto  $[-1, +1]$ , making **non** composable with the other operators.

---

## Precedent in Buddhist logic

Indian and Tibetan Buddhist philosophers identified two forms of negation:

- **Paryudasa-pratisedha** (affirming negation) – negates a predicate while implying a positive alternative. “The pot is not blue” implies it is some other color. This maps to **not**.
- **Prasajya-pratisedha** (non-affirming negation) – simply removes an attribution without positing anything in its place. “Phenomena lack inherent existence” does not assert they have some other kind of existence. This maps to **non**.

The distinction is central to Madhyamaka philosophy. When Nagarjuna argues that phenomena are “empty” (shunya), he intends prasajya – the removal of a false attribution, not the assertion of a new property called “emptiness.” Emptiness itself is empty. The negation is supposed to leave nothing behind for the mind to grasp.

Chandrakirti and later commentators insisted that this kind of negation resists formalization: any definition of “a negation that posits nothing” risks becoming a positive assertion in its own right. Tsongkhapa’s attempt – “a negation whose negandum is removed without anything posited in its place” – drew criticism from Gorampa precisely on these grounds: the definition itself seems to affirm something about what remains. The act of saying “nothing is posited” posits something. Buddhist logicians spent centuries circling this recursion without landing on a formulation that satisfied all parties.

---

## Why $1 - 2|a|$ is the right formula

1. **Symmetry of extremes.**  $\text{non}(+0.9) = \text{non}(-0.9) = -0.8$ . Strong belief and strong disbelief are treated identically. This maps precisely to the Madhyamaka rejection of both eternalism (strong positive assertion) and nihilism (strong negative assertion) as extreme views. Both are certainties; prasajya treats them the same.

**2. Ignorance yields maximum openness.**  $\text{non}(0) = +1$ . The non-affirming negation of “I don’t know” is maximum openness. This resonates with the Madhyamaka teaching that not-knowing, when held correctly, is not a deficit but a clearing. The old formula mapped  $0 \rightarrow 0$ , treating ignorance as inert.

---

## Fuzzy logic interpretation

In standard fuzzy logic on  $[0, 1]$ , the complement of a membership value  $a$  is  $1 - a$ . WikiOracle’s certainty scale  $[-1, +1]$  encodes both direction (sign) and strength (magnitude). The operation  $1 - 2|a|$  applies the standard fuzzy complement to the *strength* of certainty (via  $1 - |a|$ ), then rescales back to  $[-1, +1]$  (via  $2x - 1$ ). This is the natural fuzzy-logical reading of “negate the commitment without asserting the opposite”:

- Fuzzy affirming negation (**not**): negate the *value* – flip the sign, preserve the magnitude. You get the complementary claim.
  - Fuzzy non-affirming negation (**non**): negate the *strength* – take the fuzzy complement of  $|a|$ , rescaled to the certainty range. You get a measure of openness, not a complementary claim.
- 

## Relation to the Madhyamaka problem

WikiOracle’s **non** does not solve Chandrakirti’s problem. It translates it.

Prasajya-pratisedha is supposed to be a negation that posits nothing – not even a measurement, not even a degree.  $\text{non}(a) = 1 - 2|a|$  models *degree of epistemic openness*. That is a formal quantity, not a metaphysical void. The formula avoids the recursion that plagued Buddhist logicians because it is extensional – defined by what it computes, not by what it means to negate without affirming. But this is a change of domain, not a resolution. The philosophical question of whether a truly positionless negation can be formalized remains open. What WikiOracle provides is a metric translation that preserves the key structural features (sign erasure, symmetry of extremes, openness of ignorance) while operating in a domain where those features can be computed and composed.

---

## Expressive necessity: why {and, or, not} is incomplete without non

This section shows that **non** is not merely a philosophical ornament. It is *necessary* for the logic to express certain functions, and *sufficient* (together with {and, or, not}) to express a large and natural class.

### The regularity barrier

In Strong Kleene logic, the operators {and, or, not} have a structural constraint: they are all **regular** (also called **normal**). A function  $f$  is regular if, when every input is set to the middle value  $U$  (certainty = 0), the output is also  $U$ .

Check:

- $\text{and}(0, 0) = \min(0, 0) = 0$  (OK)
- $\text{or}(0, 0) = \max(0, 0) = 0$  (OK)
- $\text{not}(0) = -0 = 0$  (OK)

Composition preserves regularity: if  $f$  and  $g$  are regular, so is  $f \circ g$ . Therefore *every* function expressible from {and, or, not} is regular.

But  $\text{non}(0) = +1 \neq 0$ . So **non** is **not** regular.

**Theorem.** **non** cannot be expressed using {and, or, not} alone.

*Proof.* Every function in the clone generated by {and, or, not} is regular. **non** is not regular. QED.

This is the formal analogue of a structural distinction that Buddhist logicians identified but could not formalize in their own terms.

### What non adds: the detection functions

In discrete ternary logic ( $\{T, U, F\} = \{+1, 0, -1\}$ ), **non** acts as a **detector for uncertainty**:

- $\text{non}(T) = \text{non}(+1) = -1 = F$
- $\text{non}(U) = \text{non}(0) = +1 = T$
- $\text{non}(F) = \text{non}(-1) = -1 = F$

That is:  $\text{non}(x) = T$  if and only if  $x = U$ . This is the detection function **J\_U**.

From **J\_U** and the existing operators, we can construct the other two detectors:

- **J\_T(x) = and(x, not(non(x)))**: detects whether  $x = T$ .
  - $x=T$ :  $\text{and}(T, \text{not}(F)) = \text{and}(T, T) = T$  (OK)
  - $x=U$ :  $\text{and}(U, \text{not}(T)) = \text{and}(U, F) = F$  (OK)
  - $x=F$ :  $\text{and}(F, \text{not}(F)) = \text{and}(F, T) = F$  (OK)
- **J\_F(x) = and(not(x), not(non(x)))**: detects whether  $x = F$ .
  - $x=T$ :  $\text{and}(F, \text{not}(F)) = \text{and}(F, T) = F$  (OK)
  - $x=U$ :  $\text{and}(U, \text{not}(T)) = \text{and}(U, F) = F$  (OK)
  - $x=F$ :  $\text{and}(T, \text{not}(F)) = \text{and}(T, T) = T$  (OK)

With **J\_T**, **J\_U**, and **J\_F** available, we can build **case expressions**: “if  $x = T$  then  $A$ , if  $x = U$  then  $B$ , if  $x = F$  then  $C$ ” for any constants  $A, C \in \{T, F\}$ :

$\text{or}(\text{and}(\text{J}_T(x), A), \text{or}(\text{and}(\text{J}_U(x), B), \text{and}(\text{J}_F(x), C)))$

### The completeness result

**Theorem.**  $\{\text{and}, \text{or}, \text{not}, \text{non}\}$  can express every function  $f: \{T, U, F\}^n \rightarrow \{T, F\}$ .

*Proof sketch.* Given any  $f$  whose output is always definite ( $T$  or  $F$ ), express it as a disjunction over all input tuples where  $f$  returns  $T$ . Each such tuple can be detected using **J\_T**, **J\_U**, **J\_F** on individual variables, combined with **and**. The disjunction of these detections yields  $f$ . QED.

The one thing  $\{\text{and}, \text{or}, \text{not}, \text{non}\}$  *cannot* produce is  $U$  as output from definite inputs – because all four operators, given inputs in  $\{T, F\}$ , produce outputs in  $\{T, F\}$ . This is arguably correct:  $U$  represents genuine uncertainty, and should not be manufactured from certain data.

## A Two-Axis Epistemic Algebra

The four operators constitute a two-axis epistemic algebra:

- **Axis 1: belief polarity** – handled by **not**. Flips the sign; preserves magnitude. Operates on the direction of commitment.
- **Axis 2: commitment strength** – handled by **non**. Erases the sign; inverts magnitude. Operates on how strongly anything is held, regardless of direction.

**and** and **or** combine values along both axes simultaneously (min and max over signed certainty). **not** and **non** decompose the axes: one rotates direction, the other measures grip.

The formal results above establish three things:

1. **non** is not derivable from the classical ternary operators  $\{\text{and}, \text{or}, \text{not}\}$ . It breaks the regularity barrier.
2. Adding **non** yields bivalent functional completeness:  $\{\text{and}, \text{or}, \text{not}, \text{non}\}$  can express every function  $f: \{T, U, F\}^n \rightarrow \{T, F\}$ .

3. **non** enables *detection* of uncertainty rather than mere propagation. Without it, Kleene logic can pass uncertainty through but can never see it.

This is a genuine structural enrichment of Strong Kleene logic.

# Training

This document covers the full training infrastructure for WikiOracle’s NanoChat integration: how raw data is preprocessed into structured training examples, how DegreeOfTruth governs learning, the dynamic systems interpretation, and the online training pipeline that ties it all together.

## DegreeOfTruth (DoT)

DegreeOfTruth is a bipolar scalar on  $-1 .. +1$  that measures how well a user’s TruthSet agrees with the server’s collected truth.

`DegreeOfTruth = 2 × mean(agreement_i) - 1` for shared entries

where:

`agreement_i = 1 - |server_trust_i - client_trust_i| / 2`

The bipolar range encodes both true and false statements:

- **DoT = +1**: the user’s claims fully agree with the server – the exchange is true. Train at full learning rate.
- **DoT = -1**: the user’s claims fully contradict the server – the exchange is false. Train at full learning rate (learning what is *not* true is as valuable as learning what *is* true).
- **DoT ≈ 0**: no shared entries, or perfect cancellation – nothing to learn. Skip training.

Both poles (+1 and -1) train at full strength via |DoT|; only the zero crossing results in a skip. The sign encodes direction (agree/disagree), not magnitude.

This is a placeholder. A future version should incorporate `compute_derived_truth` (operator propagation) before comparison.

## Dynamic Systems Perspective

With a bipolar DegreeOfTruth ( $-1 .. +1$ ), the training loop forms a **dynamic equation with both poles and zeros**: DoT = +1 and DoT = -1 are attracting poles where the system learns at full strength (truths and refuted falsehoods respectively), while DoT = 0 is a zero – an equilibrium point where no learning occurs.

This structure resembles a **Hopfield network**, where the energy landscape has stable attractors (memorised patterns) and unstable saddle points. In our system:

- The **TruthSet** plays the role of the weight matrix, encoding the collective memory of what is true and what is false.
- Each **training step** is a state transition that pushes the model toward one of the attractors (truth or refutation).
- The **zero crossing** (DoT ≈ 0) is the energy barrier between attractors – the point of maximum uncertainty where the system has insufficient signal to commit to either direction.

As the server TruthSet accumulates entries from multiple users, the poles and zeros of this dynamic equation shift. The slow-moving average merge ensures that attractors are stable under small perturbations

(anti-capture), while strong consensus can still move the landscape over time. This is analogous to the annealing process in Hopfield networks, where the energy landscape gradually settles into deeper minima as more patterns are stored.

### Zero-Mean Balance

The DoT-annealed training algorithm has a **zero-mean balance** property: over many interactions with diverse DoT values, the expected net gradient contribution tends to zero. This arises because:

- DoT = +1 and DoT = -1 both train at full strength but push in opposite directions (learning truth vs. learning falsehood).
- DoT near 0 contributes nearly nothing (the sigmoid zero-crossing).
- Over a diverse population of users, the average DoT tends toward zero if the TruthSet is balanced.

This is directly analogous to the **symmetric energy wells** of Hopfield networks. In a Hopfield network, stored patterns and their complements are both stable attractors. In our system, truths and refuted falsehoods are both stable attractors, and the zero-crossing is the energy barrier between them.

The EMA weight anchoring adds a third stabilizing force: regardless of the DoT distribution, the model is always gently pulled back toward its checkpoint state. This is analogous to the **temperature decay** in simulated annealing – as training progresses, the system becomes increasingly resistant to perturbation while allowing deeper learning within established wells.

### Sigmoid Warmup as Annealing Schedule

The sigmoid warmup schedule serves as a **cooling schedule** for the annealing process. When online training is first enabled:

1. The TruthSet is empty or sparse – DoT values are unreliable.
2. The warmup suppresses the learning rate to near-zero.
3. As interactions accumulate, the TruthSet gains signal.
4. The warmup ramps up, allowing the model to learn from now-reliable DoT values.
5. At steady state (step » warmup\_steps), the warmup factor is ~1.0 and training proceeds at full configured strength.

This mirrors the annealing schedule in physical systems: high temperature (high exploration, low commitment) → low temperature (low exploration, high commitment to learned patterns).

### Sensation – Preprocessing Pipeline

`bin/sensation.py` transforms plain-text conversations into XML-tagged training data so that NanoChat learns WikiOracle’s structured protocol. The name follows the epistemological pipeline: **Sensation** → **Perception** → **Cognition** – raw input data (sensation) is structured and tagged before it reaches the model (cognition).

Sensation works for both batch retagging of the NanoChat SFT corpus (`identity_conversations.jsonl`, ~14K conversations) and dynamic training examples from the online training pipeline.

### JSONL Record Types

The output JSONL uses four record types, splitting the client identity into separate User and Server records:

| Type                      | Tag                               | Purpose                                                                                  |
|---------------------------|-----------------------------------|------------------------------------------------------------------------------------------|
| <code>user</code>         | <code>&lt;User&gt;</code>         | User identity – username, uid, timestamp                                                 |
| <code>server</code>       | <code>&lt;Server&gt;</code>       | Server identity – name, version, timestamp                                               |
| <code>conversation</code> | <code>&lt;Conversation&gt;</code> | Messages with <code>&lt;Q&gt;</code> (query) and <code>&lt;R&gt;</code> (response) pairs |

| Type  | Tag     | Purpose                                           |
|-------|---------|---------------------------------------------------|
| truth | <Truth> | Extracted factual claims with trust and spacetime |

Inside message content, user messages are wrapped in <Q>...</Q> and assistant messages in <R>...</R>. Each sentence within a message is independently classified as <fact> or <feeling>:

```
<R><feeling>That is a great question!</feeling>
<fact trust="0.5"><place>Paris</place>Paris is the capital of France.</fact>
<feeling>I hope that helps.</feeling></R>
```

## Korzybski IS Detection

Alfred Korzybski (*Science and Sanity*, 1933) observed that the English copula “is” conflates several distinct relations:

- **IS of identity:** “Socrates is a man”
- **IS of predication:** “The sky is blue”
- **IS of existence:** “There are eight planets”

Each asserts something verifiable about the world – a *fact* bound to a specific spacetime context. “The cup is on the table” is only true at a particular place and time; at a different spacetime it may not be.

The heuristic classifier in `sensation.py` detects these patterns:

| Subtype      | Pattern                  | Example                      |
|--------------|--------------------------|------------------------------|
| Identity     | “X is/are [a/an/the] Y”  | “Socrates is a man”          |
| Predication  | “X is/are ADJ”           | “The sky is blue”            |
| Existence    | “there is/are X”         | “There are 8 planets”        |
| Mereological | “X contains/includes Y”  | “Water contains hydrogen”    |
| Quantity     | “X has/have N Y”         | “I have 3 cats”              |
| Definition   | “X is called/known as Y” | “A polygon is defined as...” |

Sentences without an IS pattern, or with subjective markers (“I think”, “maybe”, “might be”), questions, or meta-discourse (“That’s a great question”) default to <feeling>. Auto-detected facts receive `trust=0.5` – a conservative default that flags them for future verification. Spatiotemporal binding is expressed via <place> and <time> child elements inside <fact> or <feeling> tags.

## Usage

Batch-convert a corpus:

```
make preprocess
# or: python bin/sensation.py corpus input.jsonl output.jsonl
```

Classify a single sentence:

```
python bin/sensation.py tag "Paris is the capital of France."
# → Classification: fact (identity)
# → Tagged: <Q><fact trust="0.5">Paris is the capital of France.</fact></Q>
```

In the online training pipeline, `response.py` calls `preprocess_training_example()` automatically before each /train POST, so all training examples are XML-tagged without manual intervention.

## Online Training

### Purpose

Enable continuous online training of NanoChat where every interaction can trigger a weight update. The learning rate is governed by DegreeOfTruth (see above) which evaluates how well the user’s claims fit the collective evidence.

WikiOracle accomplishes this by:

1. Maintaining a **server-owned TruthSet** (`truth.xml`) that accumulates facts from all users.
2. Computing a **DegreeOfTruth** ( $-1 \dots +1$ ) per interaction.
3. Using  $|\text{DegreeOfTruth}|$  to modulate the **learning rate** of a one-step online training pass in NanoChat.

Conversations are **not** stored on the server. Only **knowledge** truth entries are retained. The server TruthSet contains knowledge facts, operators, authorities, and references – no feelings, provider entries, or **news facts** (spatiotemporally bound observations).

News facts (those with `<place>` or `<time>` child elements carrying real values) are session-only. Persisting them would risk “worldline capture” – an observer could reconstruct a user’s physical trajectory through spatiotemporal observations. The `filter_knowledge_only()` function in `bin/truth.py` enforces this boundary.

### User Identity

Each user is identified by a pseudonymous GUID derived deterministically from `client_name` in the state file (UUID-5 in the WikiOracle namespace). The stable value is stored as `header/client_id` in XML (the runtime dictionary exposes it as `client_id`) and is used when merging truth entries into the server corpus.

### Pipeline

The pipeline is staged so the user gets a response first; truth merging and training happen after the response is delivered.

#### Stage 1 – Respond

1. Receive the user’s query and TruthSet.
2. Use truth entries for RAG as usual.
3. Return the response to the user.

#### Stage 2 – Compute DegreeOfTruth

4. Score the user’s TruthSet against the server’s current truth (formula above).

#### Stage 3 – Update server TruthSet

5. Filter client truth per the Entanglement Policy (Freedom.md):
  - When `store_concrete` is false (default), only universal facts pass through (`filter_knowledge_only()`).
  - Entries with identifiable content are always filtered regardless of `store_concrete` (`detect_identifiability()`).
  - Feelings never reach the merge (`_is_server_storable()` rejects them).
  - Operators may compose facts or feelings as operands.
  - Feelings are also stripped from training messages (`strip_feelings_from_training()` in `bin/sensation.py`).
6. Merge the surviving truth entries into the server TruthSet (`truth.xml`):
  - **Match found:** nudge the server entry’s trust toward the incoming value using a slow-moving average: `server_trust += merge_rate * (client_trust - server_trust)`
  - **No match:** insert the entry with the stated trust value.
  - Entries are restricted to facts, operators, authorities, and references. Feelings and provider entries are not stored.

### Stage 3a – TruthSet Trimming

When the server TruthSet exceeds `truth_max_entries` (default 1000), the merge step trims the table by removing entries with `|trust|` closest to 0.0 (no information value), keeping entries with highest `|trust|` (strongest signal, positive or negative). This is checked during the merge step, not as a separate operation. The trim count is logged.

The `truth_max_entries` parameter is configured under `server.training` and defaults to 1000. It remains available through the XML config/editor; the current Settings dialog does not expose it as a separate control.

### Stage 4 – Tag and Train

7. Preprocess the training example through Sensation (`sensation.py`) to add `<Q>/<R>` and `<fact>/<feeling>` XML tags.
8. Strip `<feeling>` blocks from training messages (`strip_feelings_from_training()` in `bin/sensation.py`) – feelings must never train model parameters (Entanglement policy, Freedom.md).
9. Call NanoChat’s online training endpoint (POST `/train`) with the tagged prompt, DegreeOfTruth, and training hyperparameters.

### Device Configuration

Online training runs on the device specified by `server.training.device` in the config file (`config.xml`). Valid values:

- `cpu` (default) – safe for the WikiOracle production server
- `cuda` – use NVIDIA GPU if available
- `mps` – Apple Metal Performance Shaders (macOS)
- `auto` – probe CUDA → MPS → CPU and use the best available

The model is moved to the training device for the gradient step, then moved back to the inference device afterward.

### Training Algorithm – DoT-Annealed Selective Training

The `/train` endpoint (`bin/nanochat_ext.py`) implements a carefully designed online training algorithm that prevents weight collapse while enabling meaningful learning from each interaction.

**Consistent AdamW Optimizer** All parameter groups use **AdamW** consistently. The batch training regime uses Muon (Newton-Schulz orthogonalization) for transformer matrices, but online training uses AdamW for all groups because:

1. **No persistent optimizer state** – the optimizer is created fresh each `/train` call. Muon’s advantage comes from accumulated momentum; without persistent state, its Newton-Schulz orthogonalization provides limited benefit.
2. **Effectively sign-SGD** – AdamW without momentum history is effectively sign-SGD: simpler, faster, well-understood.
3. **Independent interactions** – each `/train` call is fully independent. A bad gradient cannot poison future steps because there is no momentum history to contaminate. The effective step size is bounded by `1r`.

**Parameter Groups** The optimizer creates six parameter groups that mirror the production training regime in `nanochat/nanochat/gpt.py:GPT.setup_optimizer()`:

| Group                | Base LR | Parameters                                      |
|----------------------|---------|-------------------------------------------------|
| <code>lm_head</code> | 0.0027  | Output projection weights (language model head) |
| <code>wte</code>     | 0.136   | Token embedding weights                         |

| Group                      | Base LR | Parameters                                                         |
|----------------------------|---------|--------------------------------------------------------------------|
| <code>value_embeds</code>  | 0.136   | Value residual stream embeddings                                   |
| <code>resid_lambdas</code> | 0.005   | Per-layer residual scaling scalars                                 |
| <code>x0_lambdas</code>    | 0.5     | Skip-connection blending scalars                                   |
| <code>transformer_h</code> | 0.02    | All transformer block matrix parameters<br>(attention, MLP, norms) |

Parameters not matching any named group are included in `transformer_h`. All groups use the same AdamW optimizer – no Muon.

**Learning Rate Modulation** The effective learning rate for each parameter group is computed as:

$$\text{lr\_effective} = \text{lr\_base} \times \text{lr\_scale}$$

where:

$$\text{lr\_scale} = (\text{truth\_weight} \times |\text{DoT}| + (1 - \text{truth\_weight})) \times \text{sigmoid\_warmup}(\text{step})$$

The `truth_weight` parameter (0.0-1.0) controls how much DoT gates the learning rate:

| <code>truth_weight</code> | <code>lr_effective</code>                              | Behavior                                                |
|---------------------------|--------------------------------------------------------|---------------------------------------------------------|
| 0.0                       | <code>lr_base × warmup</code>                          | Vanilla SFT – full LR regardless of DoT. No truth bias. |
| 0.5                       | <code>lr_base × (0.5 × abs(DoT) + 0.5) × warmup</code> | Half-gated – DoT attenuates but never fully suppresses. |
| 1.0                       | <code>lr_base × abs(DoT) × warmup</code>               | Fully DoT-gated – zero DoT means zero learning.         |

`truth_weight` is configured in `server.truthset` and is not a separate control in the current Settings dialog. At `truth_weight=0`, truth sources are omitted from provider grounding and DoT does not gate training. At `truth_weight=1`, grounding is fully enabled and DoT governs learning.

**Sigmoid Warmup** The sigmoid warmup schedule prevents early random updates from corrupting the model when online training is first enabled:

$$\text{sigmoid\_warmup}(\text{step}) = 1 / (1 + \exp(-k \times (\text{step} - \text{midpoint})))$$

| Step                       | Warmup value | Effect                                           |
|----------------------------|--------------|--------------------------------------------------|
| 0                          | ~0.007       | Nearly zero – first interactions barely train    |
| midpoint                   | 0.5          | Half strength                                    |
| $2 \times \text{midpoint}$ | ~0.993       | Nearly full strength – training ramp is complete |

The `warmup_steps` parameter (default 50) is the sigmoid midpoint. The steepness parameter `k` is fixed at 0.1.

This schedule ensures that the first few interactions after enabling online training have minimal weight impact, allowing the TruthSet to accumulate signal before the model commits to learning from it.

**Gradient Clipping** After the backward pass, gradients are clipped to prevent catastrophic single-step weight changes:

```
torch.nn.utils.clip_grad_norm_(all_params, max_norm=grad_clip)
```

The `grad_clip` parameter (default 1.0) bounds the global gradient norm. The actual gradient norm after clipping is returned in the `/train` response as `grad_norm` for monitoring.

If `grad_norm` consistently hits the clip threshold, this indicates either: (a) the learning rate is too high for the current data, or (b) the training example is an outlier. Both are handled gracefully by clipping – the step still proceeds, just with bounded magnitude.

**EMA Weight Anchoring (Anti-Capture)** After each optimizer step, model weights are blended back toward the **checkpoint anchor** using exponential moving average:

```
for p, anchor in zip(model.parameters(), anchor_params):  
    p.data.lerp_(anchor, anchor_effective)
```

where:

```
anchor_effective = anchor_decay * truth_weight
```

The anchor weights are the original checkpoint weights, initialized on the first `/train` call. The `anchor_decay` parameter (default 0.001) controls the blend-back rate.

Key properties:

- **truth\_weight=0**: `anchor_effective = 0` – no anchor pull. Weights drift freely (vanilla SFT mode).
- **truth\_weight=1**: `anchor_effective = anchor_decay` – full anchor pull. Weights are always tugged back toward the checkpoint.
- The anchor prevents **gradual drift** while allowing meaningful learning. Over many steps, the weights can move significantly from the checkpoint, but each individual step is bounded.
- **Reset via make nano\_restart** – reloads both the model and the anchor, resetting the training state.

The anchor is stored in `app.state.anchor_params` as a list of cloned parameter tensors. The step count is stored in `app.state.train_step_count`.

## Training Flow (Per /train Call)

POST `/train`

```
|– Clamp DoT to [-1, +1], truth_weight to [0, 1]  
|– If truth_weight > 0 and |DoT| < 1e-6 -> skip (no signal)  
|– Acquire model worker from pool  
|– Tokenize messages (bos + user_start/end + assistant_start/end)  
|– If < 2 tokens -> skip (empty)  
|– Initialize EMA anchor weights (first call only)  
|– Move model to training device  
|– Build 6 parameter groups (fresh each call)  
|– Compute lr_scale = (tw x |DoT| + (1 - tw)) x sigmoid_warmup(step)  
|– Scale each group's LR: lr_base x lr_scale  
|– Create fresh AdamW optimizer  
|– Forward pass -> cross-entropy loss  
|– Backward pass  
|– Gradient clipping -> grad_norm  
|– Optimizer step  
|– EMA anchor blend-back (if truth_weight > 0)  
|– Increment step count  
|– Move model back to inference device  
`– Return {status, loss/gain, step, grad_norm}
```

The response uses key "loss" for positive DoT (learning truth) and "gain" for negative DoT (learning falsehood). Both are the cross-entropy loss value; the key name indicates the semantic direction.

## Configuration Summary

| Parameter         | Config path                       | Default | Description                                     |
|-------------------|-----------------------------------|---------|-------------------------------------------------|
| truth_weight      | server.truthset.truth_weight      | 0.7     | DoT gating strength (0=vanilla SFT, 1=full DoT) |
| warmup_steps      | server.training.warmup_steps      | 50      | Sigmoid warmup midpoint                         |
| grad_clip         | server.training.grad_clip         | 1.0     | Max gradient norm                               |
| anchor_decay      | server.training.anchor_decay      | 0.001   | EMA blend-back rate                             |
| truth_max_entries | server.training.truth_max_entries | 1000    | Max server TruthSet size                        |
| device            | server.training.device            | "cpu"   | Training device                                 |

See Config.md Section Server for the full configuration reference.

**Truth-Modulated Loss (MentalModel)** In the basicModel's `MentalModel`, the training loss is further modulated by **luminosity** and **universality** to prevent learning irrational or unkind propositions:

```
totalLoss = totalLoss * (1 + LuminosityWeight * (1 - luminosity)
                        + UniversalityWeight * (1 - universality))
```

- **Luminosity** measures truth set coherence (see Logic.md Section Luminosity). Low luminosity increases loss.
- **Universality** measures the Golden Rule via SVO/OVS swap (see Ethics.md Section Universality). Low universality increases loss.

Both weights default to 0.1, making the effect gentle. This operates independently of the DoT-annealed training described above – DoT gates the learning rate, while luminosity/universality modulate the loss magnitude.

See Config.md Section MentalModel Configuration for the XML parameters.

## SFT Corpus Preparation

The `prepare_sft_corpus()` function in `bin/sensation.py` provides batch conversion of the NanoChat SFT corpus to XML-tagged format with feelings stripped. This is the batch equivalent of `preprocess_training_example()` and is used when retraining NanoChat from scratch with WikiOracle's protocol:

```
make build_sft
# or: python bin/sensation.py sft input.jsonl output.jsonl
```

Each input line is a JSON array of `{"role": ..., "content": ...}` message dicts. Output lines are the same shape but with content XML-tagged using `<Q>/<R>` and `<fact>/<feeling>` tags, with feelings stripped (matching the online training pipeline).

## Server TruthSet

The server TruthSet is stored as `truth.xml` in the same XML format used for state files (WikiOracle State). Each stored entry is a typed truth element:

```
<fact id="..." title="..." DoT="0.8" time="..." place="Athens">
  All men are mortal.
</fact>
```

**Resolution:** Before entries reach the server TruthSet, they are resolved by `resolve_entries()` in `bin/truth.py`:

- `<reference>` → `<fact src="domain">text</fact>` (domain preserved for deeper lookup)
- `<authority>` → list of `<fact src="domain">content</fact>` (fetched from remote, trust scaled)
- `<provider>` → `<feeling>` (provider responses are treated as feelings until providers can report truth claims with DoT)
- `<fact>`, `<feeling>`, `<logic>` → pass through unchanged

Entry types stored after resolution: `<fact>` (knowledge – no `<place>`/`<time>` children) and `<logic>` entries (operators wrapped in `<logic><and|or|not|non>...</logic>`).

Entry types **not** stored: `<feeling>`, `<provider>`, unresolved `<reference>`, unresolved `<authority>`, and (when `store_concrete` is false) news facts with `<place>` or `<time>` child elements. Content matching identifiability patterns (PII) is always excluded.

News facts are spatiotemporally bound – persisting them risks worldline capture. Whether to store them is a user choice controlled by `store_concrete` in `config.xml` (default false), consistent with Zero-Knowledge / Selective Disclosure principles. See `filter_knowledge_only()` in `bin/truth.py` and `detect_identifiability()` for PII detection. See `Freedom.md` for the full policy.

The server TruthSet includes the user GUID as a trust entry, so the server can track per-user trust alongside factual claims.

## Anti-Capture

The online training system has multiple layers of defense against weight collapse and capture by any single user:

### TruthSet level:

- Entries are merged with a **slow-moving average** (`merge_rate`, default 0.1), so no single user can instantly override collective truth.
- Disproven entries naturally drift toward `-1` as contradicting evidence accumulates from other users.
- **TruthSet trimming** (`truth_max_entries`, default 1000) removes low-signal entries (`|trust|` near 0), keeping the TruthSet focused on strong signal.

### Training level:

- **DegreeOfTruth gates the learning rate** – claims that diverge from consensus (DoT near 0) have minimal training impact.
- **Gradient clipping** (`grad_clip`, default 1.0) prevents any single training step from making catastrophic weight changes.
- **EMA weight anchoring** (`anchor_decay`, default 0.001) continuously blends weights back toward the checkpoint, preventing gradual drift. The anchor pull is scaled by `truth_weight`, so at full truth-gating the model is always tugged back toward its initialized state.
- **Sigmoid warmup** (`warmup_steps`, default 50) prevents the first few interactions from corrupting weights before the TruthSet has accumulated sufficient signal.
- **Fresh optimizer per call** – no persistent momentum state means a bad gradient cannot poison future steps. Each interaction is independent.
- **Consistent AdamW** – without accumulated Muon state, AdamW is effectively sign-SGD with bounded step size.

### Operational level:

Manual rollback is available via Makefile targets:

- **make checkpoint-pull** – rsync SFT checkpoints from the remote WikiOracle server to `output/checkpoints/` for safekeeping.
- **make checkpoint-push** – restore checkpoints from backup, then **make wo-restart** to reload weights.

The intended workflow: pull a checkpoint before enabling online training, then push to restore if capture is detected.

## Dissonance Detection and Pluralistic Truth (TODO)

Detecting and resolving dissonance within the server TruthSet is left for future work. The goal is to support a higher-dimensional truth-space where contradictory claims can coexist when they originate from different perspectives.

For example: “the world was created in seven days” and “the world was created over millions of years” could both be maintained as true from their respective perspectives. This requires embedding perspective alongside truth value so that the TruthSet becomes a manifold rather than a flat list.

In the current consensus model, a DoT  $\approx 0$  simply means “nothing to learn” and the training step is skipped. In a future **pluralistic** model – where the same claim can be true in context `c_1` and false in context `c_2` – a DoT of 0 may instead indicate that **user feedback is needed** to disambiguate which context applies before training should proceed.

Possible approaches include context/perspective tags on entries, truth-space embeddings with frame clustering, conditional truth values indexed by worldview, or explicit user prompts to resolve ambiguity when the TruthSet produces conflicting signals.

## OpenClaw Integration

OpenClaw is WikiOracle’s multi-channel front-end (Slack, Discord, Telegram, etc.). The TypeScript extension at `openclaw/extensions/wikioracle/` registers WikiOracle as a native OpenClaw provider by spawning `bin/wo` for each query.

The extension provides three capabilities:

1. **Provider** – WikiOracle appears in OpenClaw’s provider selector alongside OpenAI, Anthropic, etc. Selecting it routes all messages through the WikiOracle server’s full pipeline.
2. **Command** (`/wo <message>`) – Direct CLI-style access from any OpenClaw channel, bypassing the agent/LLM layer.
3. **Tool** (`wikioracle_query`) – Lets OpenClaw agents invoke WikiOracle programmatically during agentic runs.

The message flow through the training pipeline:

1. OpenClaw receives a message from any channel (Slack/Discord/etc.).
2. The wikioracle extension spawns `bin/wo` with the message.
3. `bin/wo` sends `POST /chat` to the WikiOracle server.
4. WikiOracle responds (Stage 1: provider routing, truth RAG).
5. Stages 2-4 execute server-side: DoT computation, truth merge, Sensation preprocessing, and NanoChat online training.
6. `bin/wo` prints the response to stdout; the extension captures it and relays it back to the originating channel.

In stateful mode (default), the WikiOracle server owns session state – conversation context persists across messages without client-side storage. In stateless mode, state is serialized to a local XML file via `bin/wo -f`.

The training pipeline treats OpenClaw messages identically to direct HTTP or web UI clients – the same DoT computation, TruthSet merge, Sensation preprocessing, and `/train` call apply. The `bin/wo` CLI is transparent to the training system.

## Extension configuration

```
// In OpenClaw's config file (~/.openclaw/config.json5 or project-level)
{
  plugins: {
    entries: ["wikioracle"],
    wikioracle: {
      woPath: "/path/to/WikiOracle/bin/wo",
      serverUrl: "https://127.0.0.1:8888",
      insecure: true,    // skip TLS verification for local dev
      stateful: true,    // server owns session state
      token: "...",      // optional bearer token
    },
  },
}
```

See `openclaw/extensions/wikioracle/openclaw.plugin.json` for the full config schema.

## Server TruthSet Visibility (Debug Mode)

When `DEBUG_MODE` is enabled and online training is active, the `/chat` response includes a `server_truth` key containing the server's TruthSet entries formatted as authority-tagged entries:

```
{
  "server_truth": [
    {
      "type": "authority",
      "id": "entry-id",
      "title": "...",
      "trust": 0.8,
      "content": "<fact>...</fact>",
      "source": "wikioracle"
    }
  ]
}
```

The client displays these entries in the TruthSet with a visual marker (server badge, different border style). Entries are deduplicated by `id` on each debug refresh.

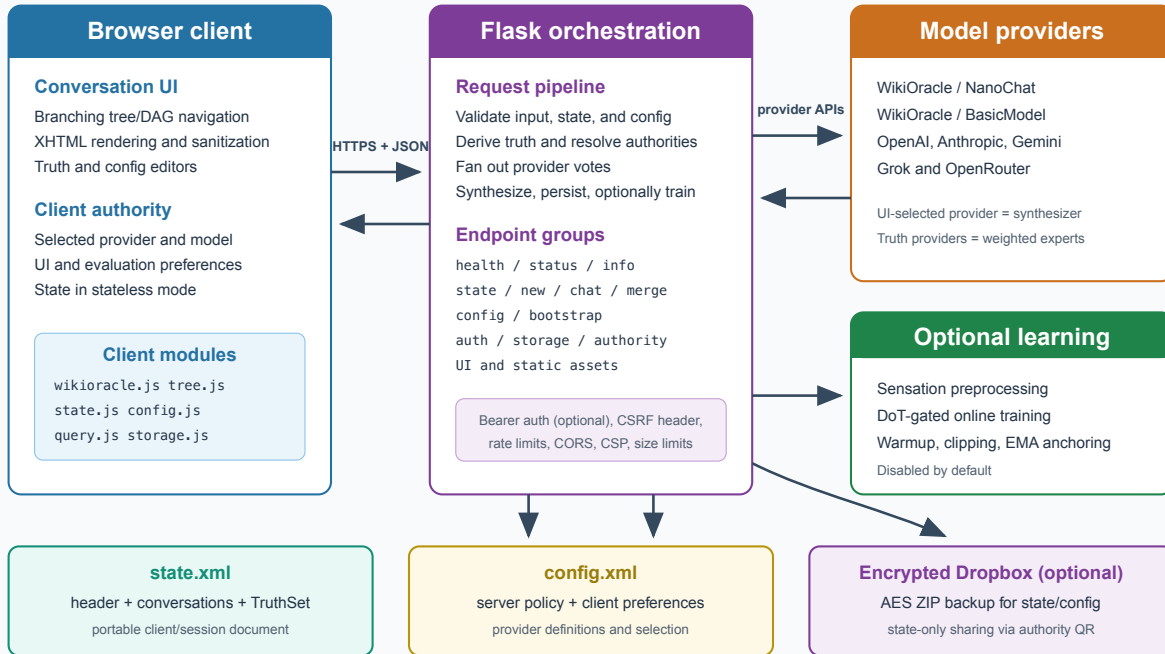

The `server_id` field in `config.xml` under `<server>` provides a stable identifier for this server instance (default: `"wikioracle"`).

# Implementation

## System Overview

WikiOracle is a Flask orchestration layer between a browser/CLI client and one or more model providers. It combines a recursive conversation graph, typed truth, provider voting, encrypted storage integration, and optional online learning.

## WikiOracle architecture

## Components

| Layer              | File(s)                              | Responsibility                                                                                                                           |
|--------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Flask application  | <code>bin/wikioracle.py</code>       | Routes, runtime contracts, authentication/CSRF/rate limiting, Dropbox OAuth, encrypted storage, and static UI serving                    |
| Configuration      | <code>bin/config.py</code>           | Baseline/override XML loading, provider registry, client-safe projection, environment/runtime settings, XML writer                       |
| State              | <code>bin/state.py</code>            | XML/legacy JSON loading, tree/DAG normalization, selection, serialization, atomic writes, collision-safe merge                           |
| Conversation graph | <code>bin/graph.py</code>            | Lookup, ancestry, context paths, selection, flattening, and traversal helpers                                                            |
| Response pipeline  | <code>bin/response.py</code>         | Prompt bundles, truth/provider coordination, adapter calls, HME fan-out, conversation construction, online-training dispatch             |
| Truth engine       | <code>bin/truth.py</code>            | Typed truth normalization, Strong Kleene and/or/not/non, authority/reference resolution, DoT, privacy classification, server-truth merge |
| Sensation          | <code>bin/sensation.py</code>        | Fact/feeling tagging, Korzybski IS classification, spatiotemporal labeling, corpus/SFT preparation                                       |
| NanoChat extension | <code>bin/nanochat_ext.py</code>     | /train route, DoT-annealed AdamW, warmup, gradient clipping, and EMA anchoring                                                           |
| BasicModel service | <code>basicmodel/bin/serve.py</code> | Local OpenAI-compatible BasicModel inference on port 8001 by default                                                                     |

| Layer                        | File(s)                                                | Responsibility                                                                                              |
|------------------------------|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| OpenClaw bridge              | bin/wo, openclaw/<br>extensions/wikioracle/            | CLI and provider/command/tool integration<br>for OpenClaw channels                                          |
| Browser shell                | client/index.html, client/<br>*.css                    | Settings, tree/chat panels, dialogs, editor<br>surfaces, responsive layout                                  |
| Browser controller           | client/wikioracle.js                                   | State transitions, message rendering, branching,<br>selection, provider requests                            |
| Browser<br>state/config      | client/state.js, client/<br>config.js                  | Browser persistence plus XML config conversion                                                              |
| Browser graph                | client/graph.js, client/<br>tree.js                    | Conversation merge/traversal and D3 rendering                                                               |
| Browser<br>utilities/storage | client/util.js, client/<br>storage.js, client/query.js | Editors, settings, Dropbox/QR workflow, and<br>API requests                                                 |

| Tests                        | test/test_*.py                                         | State/config roundtrip, stateless contract,<br>security, voting, truth, training, and UI-string<br>coverage |

## HTTP API

Every route is prefixed by the effective `url_prefix`. POST requests require `X-Requested-With: WikiOracle`. When `WIKIORACLE_API_TOKEN` is set, non-public routes also require the configured bearer token.

### Core and Status

| Method | Path               | Purpose                                                     |
|--------|--------------------|-------------------------------------------------------------|
| GET    | /health            | Flask liveness check                                        |
| GET    | /nanochat_status   | Probe the configured local<br>WikiOracle/NanoChat upstream  |
| GET    | /basicmodel_status | Probe BasicModel on its configured/default<br>endpoint      |
| GET    | /server_info       | Report stateless mode, prefix, and training<br>availability |
| GET    | /bootstrap         | Return seed state and client-safe config                    |
| GET    | /info              | Return state/schema/provider/startup-merge<br>diagnostics   |

### State, Chat, and Config

| Method | Path        | Purpose                              | Stateless behavior                   |
|--------|-------------|--------------------------------------|--------------------------------------|
| GET    | /state      | Read canonical or<br>in-memory state | Returns memory/seed state            |
| POST   | /state      | Replace state                        | Replaces memory state; no disk write |
| POST   | /new        | Reset to an<br>empty session         | Replaces memory state                |
| GET    | /state_size | Report local<br>state-file size      | Reports seed-file size if present    |

| Method       | Path    | Purpose                                                  | Stateless behavior                                                               |
|--------------|---------|----------------------------------------------------------|----------------------------------------------------------------------------------|
| POST/OPTIONS | /chat   | Process one conversation turn                            | Requires <code>state</code> and <code>runtime_config</code> ; returns full state |
| POST/OPTIONS | /merge  | Merge state payloads or adjacent import files            | Rejected because writes are disabled                                             |
| GET          | /config | Return the client-safe canonical config                  | Allowed                                                                          |
| POST         | /config | Replace only the <code>client</code> section and persist | Rejected because the shared server config cannot be mutated                      |

### Dropbox and Authority Storage

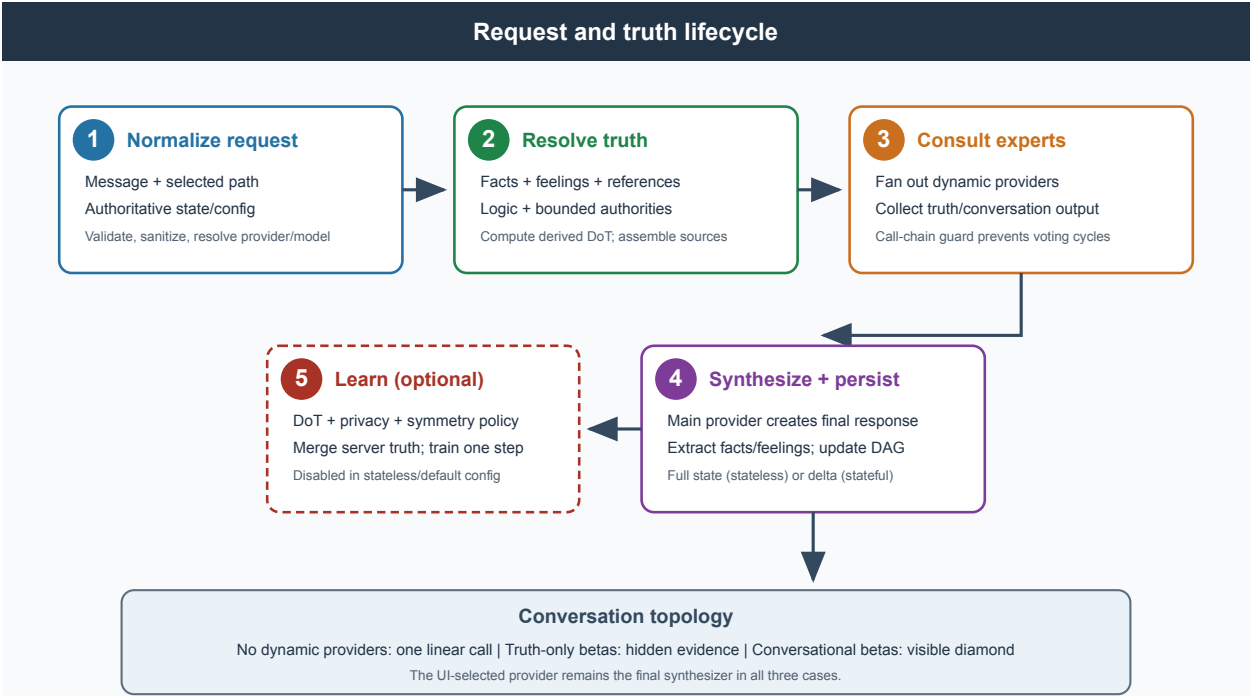

| Method | Path                     | Purpose                                                                                     |
|--------|--------------------------|---------------------------------------------------------------------------------------------|
| GET    | /auth/dropbox/start      | Begin Dropbox OAuth2                                                                        |
| GET    | /auth/dropbox/callback   | Complete OAuth2 and save tokens in the Flask session                                        |
| GET    | /auth/dropbox/status     | Report whether Dropbox is configured/connected                                              |
| POST   | /auth/dropbox/logout     | Clear Dropbox tokens from the session                                                       |
| GET    | /storage/status          | Check for encrypted config/state bundles                                                    |
| POST   | /storage/save            | Encrypt and upload state/config; optionally return authority QR data for state-only sharing |
| POST   | /storage/load            | Download, decrypt, and return/persist state or client-safe config                           |
| POST   | /authority/conversations | Fetch conversations from an authority URL, optionally with a decryption key                 |

### UI Assets

| Method | Path                        | Purpose                                                                              |
|--------|-----------------------------|--------------------------------------------------------------------------------------|
| GET    | /                           | Serve <code>client/index.html</code> without caching                                 |
| GET    | / <code>&lt;path&gt;</code> | Serve an existing asset under <code>client/</code> when its extension is allowlisted |

# Request and State Contracts

| Contract         | Client sends                                                           | Server reads                                                                    | Server returns                                | Durable authority                                                |
|------------------|------------------------------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------|------------------------------------------------------------------|
| Stateful / chat  | Message, routing IDs, query config, and optionally client truth        | State/config from disk, with supplied truth overriding state truth for the turn | Display text plus selected conversation delta | Local <code>state.xml</code> ; client retains its own truth copy |
| Stateless / chat | Message, routing IDs, complete authoritative state, and runtime config | Request only                                                                    | Display text plus complete updated state      | Browser/CLI client                                               |

The stateless contract never uses disk or a previous in-memory state as an implicit input to `/chat`. The stateful contract persists the complete updated state, but its chat response deliberately omits truth and config.

## Chat Routing

| Request fields                                      | Routing behavior                                               |
|-----------------------------------------------------|----------------------------------------------------------------|
| <code>conversation_id</code>                        | Continue an existing conversation                              |
| <code>branch_from</code>                            | Create a child branch below the specified conversation         |
| Neither                                             | Create a root conversation                                     |
| Empty message at<br>root/terminal/pending<br>branch | Create a valid continuation/branch turn without a user message |

When conversational beta providers participate, the graph becomes a diamond: a query node fans out to beta child conversations, and one final conversation is shared as a child of all participating beta nodes.

## Truth and Provider Pipeline

The pipeline does not call a `dynamic_truth()` helper. Instead, it normalizes direct sources, computes logic, resolves provider entries, and assembles one final `ProviderBundle`.

| Step                           | Key implementation                                                | Effect                                                                                              |
|--------------------------------|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Direct-source extraction       | <code>static_truth()</code> , <code>direct_truth_sources()</code> | Extract facts, feelings, and references from the client TruthSet                                    |
| Logic derivation               | <code>compute_derived_truth()</code>                              | Recompute <b>and</b> , <b>or</b> , <b>not</b> , and <b>non</b> entries and attach derived certainty |
| Authority/reference resolution | <code>bin/truth.py</code> resolvers                               | Fetch only allowlisted sources with size/depth limits                                               |
| Beta consultation              | <code>evaluate_providers()</code>                                 | Query dynamic truth providers; separate conversational and truth-only contributions                 |
| Main synthesis                 | <code>build_query()</code> , <code>_call_provider()</code>        | Send history, truth, derived evidence, and beta output to the UI-selected provider                  |
| Structured extraction          | <code>_extract_direct_truths()</code>                             | Separate <code>&lt;conversation&gt;</code> display output from returned facts/feelings              |
| Graph update                   | <code>process_chat()</code>                                       | Add a linear turn or construct a voting diamond                                                     |
| Optional learning              | <code>process_chat()</code> plus <code>nanochat_ext.py</code>     | Merge permitted truth and dispatch a bounded training step                                          |

Structural entries are not treated as prose claims. Logic yields derived DoT, authorities yield imported evidence, and providers yield expert contributions. With no dynamic provider entries, the pipeline makes one main-provider call.

## Thought-Free Mode

| Target                | Behavior                                                                                                          |
|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| External LLM adapters | Adds the non-discursive constraint prompt to the system bundle                                                    |
| BasicModel            | Sends <code>thought_free=true</code> ; the BasicModel service applies its restricted grammar path for the request |
| Browser display       | Strips supported thinking blocks before display according to client preference                                    |

The preference originates at `config.client.thought_free`, enters the query bundle, and reaches `_call_provider()`.

## Security Middleware

| Control        | Implementation                                                                     |
|----------------|------------------------------------------------------------------------------------|
| Request size   | Flask <code>MAX_CONTENT_LENGTH</code> from <code>WIKIORACLE_MAX_STATE_BYTES</code> |
| Message length | <code>WIKIORACLE_MAX_INPUT_LEN</code>                                              |
| Input guard    | <code>guard_input()</code> rejects configured prompt-injection patterns            |
| Authentication | Optional exact bearer-token match                                                  |
| CSRF           | Required <code>X-Requested-With: WikiOracle</code> on POST                         |
| Rate limit     | Sliding per-IP limit; chat and default RPM are configurable                        |
| Browser policy | Restrictive CSP and allowlisted CORS origins                                       |
| Static files   | Extension allowlist plus resolved-path containment check                           |
| State files    | Optional symlink rejection and atomic replace                                      |

## State Library Reference

| Function                                      | Purpose                                                   |
|-----------------------------------------------|-----------------------------------------------------------|
| <code>state_to_xml(state)</code>              | Serialize normalized state to typed XML                   |
| <code>xml_to_state(text)</code>               | Parse typed XML into normalized runtime state             |
| <code>atomic_write_xml(path, state)</code>    | Temporary-file, <code>fsync</code> , atomic-rename write  |
| <code>load_state_file(path)</code>            | Read XML or legacy monolithic JSON                        |
| <code>find_</code>                            | Recursive tree/DAG lookup                                 |
| <code>conversation(conversations, id)</code>  |                                                           |
| <code>get_ancestor_</code>                    | Resolve all ancestors for context/navigation              |
| <code>chain(conversations, id)</code>         |                                                           |
| <code>get_context_</code>                     | Build ordered path context                                |
| <code>messages(conversations, id)</code>      |                                                           |
| <code>add_message_to_conversation(...)</code> | Append a message                                          |
| <code>)</code>                                |                                                           |
| <code>add_child_conversation(...)</code>      | Add a branch                                              |
| <code>remove_conversation(...)</code>         | Delete a subtree                                          |
| <code>merge_llm_states(base, incoming)</code> | Merge state with deterministic collision-safe identifiers |
| <code>ensure_minimal_state(state)</code>      | Normalize required defaults and selection invariants      |

## Config

WikiOracle configuration is XML loaded by `bin/config.py` and described by `data/config.xsd`. `data/config.xml` is the shipped baseline; an optional project-root `config.xml` is deep-merged over it. Scalars and lists in the override replace baseline values, while nested dictionaries merge recursively.

## Canonical Structure

| Section                     | Authority       | Contents                                                                                                                                   |
|-----------------------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;server&gt;</code> | Operator/server | Runtime mode, truth policy, evaluation/training defaults, URL allowlist, Dropbox app credentials, provider definitions, and shared prompts |

| Section  | Authority      | Contents                                                                                                                |
|----------|----------------|-------------------------------------------------------------------------------------------------------------------------|
| <client> | Browser/client | UI preferences, per-session evaluation choices, provider/model selection, storage preference, and per-provider API keys |

```
<config xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:noNamespaceSchemaLocation="config.xsd">
  <server>...</server>
  <client>...</client>
</config>
```

The browser receives a client-safe projection. Server-only Dropbox attributes and any provider key found in `server.providers` are removed; configured provider definitions are augmented with the model choices used by the UI. Values under `client.providers`, including client-owned API keys, remain browser-visible.

## Server

### Identity and Runtime

| Field                     | Type    | Shipped value           | Description                                                                              |
|---------------------------|---------|-------------------------|------------------------------------------------------------------------------------------|
| <code>server_name</code>  | String  | <code>WikiOracle</code> | Human-readable server label; optional in the XSD                                         |
| <code>server_id</code>    | String  | <code>wikioracle</code> | Persistent server identity; a missing ID is generated in writable mode                   |
| <code>stateless</code>    | Boolean | <code>true</code>       | Disable state/config writes and require authoritative state/config on <code>/chat</code> |
| <code>url_prefix</code>   | String  | Empty                   | Prefix applied to every route for reverse-proxy deployments                              |
| <code>truthset</code>     | Section | See below               | Truth admission and grounding policy                                                     |
| <code>evaluation</code>   | Section | See below               | Provider evaluation defaults                                                             |
| <code>training</code>     | Section | See below               | Optional continuous-learning defaults                                                    |
| <code>allowed_urls</code> | Section | See below               | Outbound provider/authority allowlist                                                    |
| <code>dropbox</code>      | Element | Empty credentials       | Server-only Dropbox OAuth app attributes                                                 |
| <code>providers</code>    | Section | Six definitions         | Shared prompt fields and upstream provider definitions                                   |

Runtime precedence for the `stateless` flag is CLI `--stateless`, then `server.stateless`, then `WIKIORACLE_STATELESS`. The route prefix uses CLI `--url-prefix`, then `WIKIORACLE_URL_PREFIX`.

### TruthSet Policy

| Field                       | Type        | Default            | Description                                                                                                |
|-----------------------------|-------------|--------------------|------------------------------------------------------------------------------------------------------------|
| <code>truth_symmetry</code> | Boolean     | <code>true</code>  | Check value claims for asymmetric harm under identity exchange                                             |
| <code>store_concrete</code> | Boolean     | <code>false</code> | Permit spatiotemporally bound facts in the server TruthSet                                                 |
| <code>truth_weight</code>   | Decimal 0-1 | <code>0.7</code>   | Controls whether/how strongly TruthSet sources enter the prompt and how strongly DoT gates online learning |

| <code>truth_weight</code> | RAG behavior               | Online-learning behavior                                            |
|---------------------------|----------------------------|---------------------------------------------------------------------|
| 0.0                       | Truth sources are omitted  | DoT does not gate the learning rate; EMA anchor effect is zero      |
| 0.7                       | Default weighted grounding | DoT substantially modulates learning and anchoring                  |
| 1.0                       | Full grounding             | Learning is fully DoT-gated and uses the configured anchor strength |

## Evaluation Defaults

| Field                     | Type             | Default            | Description                                                                                |
|---------------------------|------------------|--------------------|--------------------------------------------------------------------------------------------|
| <code>temperature</code>  | Decimal 0-2      | 0.7                | Sampling temperature                                                                       |
| <code>max_tokens</code>   | Positive integer | 128                | Maximum response tokens requested from the main provider                                   |
| <code>timeout</code>      | Positive integer | 120                | Provider request timeout in seconds                                                        |
| <code>url_fetch</code>    | Boolean          | <code>false</code> | Allow URL content to be incorporated during evaluation                                     |
| <code>thought_free</code> | Boolean          | <code>false</code> | Optional server default for non-discursive output; the client has its own preference field |

The request can override provider, model, temperature, URL fetching, thought-free mode, and selected truth/training controls. Values are clamped or normalized in `process_chat()`.

## Training

Training is disabled by default and is also unavailable in stateless mode.

| Field                                  | Type                         | Default                     | Description                                                            |
|----------------------------------------|------------------------------|-----------------------------|------------------------------------------------------------------------|
| <code>enabled</code>                   | Boolean                      | <code>false</code>          | Master switch for post-response truth merge and online training        |
| <code>truth_corpus_path</code>         | String                       | <code>data/truth.xml</code> | Server truth corpus path                                               |
| <code>truth_max_entries</code>         | Integer 100-10000            | 1000                        | Maximum corpus entries before low-information trimming                 |
| <code>alpha_base</code>                | Decimal                      | 0.01                        | Base learning rate                                                     |
| <code>alpha_min</code>                 | Decimal                      | 0.001                       | Minimum learning-rate floor                                            |
| <code>alpha_max</code>                 | Decimal                      | 0.1                         | Maximum learning-rate ceiling                                          |
| <code>merge_rate</code>                | Decimal                      | 0.1                         | Moving-average rate when client truth updates an existing server entry |
| <code>device</code>                    | <code>auto, cpu, cuda</code> | <code>cpu</code>            | Online-training device                                                 |
| <code>dissonance_enabled</code>        | Boolean                      | <code>true</code>           | Enable contradiction/dissonance handling                               |
| <code>operators_dynamic_enabled</code> | Boolean                      | <code>true</code>           | Enable dynamic operator processing                                     |
| <code>warmup_steps</code>              | Positive integer             | 50                          | Midpoint of the sigmoid training warmup                                |
| <code>grad_clip</code>                 | Decimal > 0                  | 1.0                         | Maximum gradient norm                                                  |
| <code>anchor_decay</code>              | Decimal 0-1                  | 0.001                       | EMA pull toward checkpoint parameters                                  |

When `enabled=false`, the post-response DegreeOfTruth, server-truth merge, and online-training stages are skipped. Message-level fact/feeling parsing and response rendering still operate.

## Allowed URLs

`allowed_urls` is a repeated prefix allowlist used for authority lookups and dynamic provider endpoints.

| URL class            | Rule                                                                                                                                                                        |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTPS                | Allowed only when the full URL begins with a configured prefix                                                                                                              |
| Loopback HTTP        | Allowed only for <code>127.0.0.1</code> or <code>localhost</code> , and only when prefix-matched                                                                            |
| <code>file://</code> | Denied unless an explicit <code>file://</code> prefix is allowlisted; API-key file resolution is additionally confined to its data allowlist and rejects symlinks/traversal |
| Other schemes        | Denied                                                                                                                                                                      |

## Dropbox

```
<dropbox app_key="..." app_secret="..."/>
```

| Attribute               | Required by XSD | Exposure                                                                   |
|-------------------------|-----------------|----------------------------------------------------------------------------|
| <code>app_key</code>    | Yes             | Server only; removed from <code>/config</code> and <code>/bootstrap</code> |
| <code>app_secret</code> | Yes             | Server only; removed from <code>/config</code> and <code>/bootstrap</code> |

Dropbox OAuth tokens are stored in the Flask session cookie context; the encryption password supplied for a save/load operation is not stored in configuration or session state.

## Provider Definitions

Provider definitions live under `server.providers`. The element uses an explicit `<name>` child, not a `name` attribute.

## Shared Prompt Fields

| Field                             | Type   | Purpose                                        |
|-----------------------------------|--------|------------------------------------------------|
| <code>context</code>              | XHTML  | Shared system context                          |
| <code>output</code>               | String | Output-format instructions                     |
| <code>truth_context</code>        | XHTML  | Role context for truth-only beta providers     |
| <code>conversation_context</code> | XHTML  | Role context for conversational beta providers |

## Provider Fields

| Field                 | Required | Description                                                                                                                                                 |
|-----------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>     | Yes      | User-facing registry key used by client selection                                                                                                           |
| <code>type</code>     | Yes      | Adapter type: <code>wikioracle</code> , <code>openai</code> , <code>anthropic</code> , <code>gemini</code> , <code>grok</code> , or <code>openrouter</code> |
| <code>username</code> | No       | Account/display metadata                                                                                                                                    |
| <code>url</code>      | Yes      | Upstream endpoint                                                                                                                                           |
| <code>model</code>    | Yes      | Server default model                                                                                                                                        |

| Field     | Required     | Description                                                                                                                                           |
|-----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| timeout   | Yes          | Per-provider timeout                                                                                                                                  |
| streaming | Yes          | Streaming capability flag                                                                                                                             |
| api_key   | No in schema | Legacy server-side position; canonical client keys belong under <code>client.providers</code> and the server parser omits this field from definitions |

```

<providers>
  <context>Return strictly valid XHTML.</context>
  <output>Use conversation, fact, and feeling elements.</output>
  <provider>
    <name>OpenAI</name>
    <type>openai</type>
    <username>you@example.com</username>
    <url>https://api.openai.com/v1/chat/completions</url>
    <model>gpt-4o</model>
    <timeout>120</timeout>
    <streaming>>false</streaming>
  </provider>
</providers>

```

## Shipped Providers

| Name       | Type       | Shipped model             | Endpoint family                  |
|------------|------------|---------------------------|----------------------------------|
| WikiOracle | wikioracle | nanochat                  | Local OpenAI-compatible endpoint |
| OpenAI     | openai     | gpt-4o                    | OpenAI chat completions          |
| Anthropic  | anthropic  | claude-sonnet-4-6         | Anthropic messages               |
| Gemini     | gemini     | gemini-2.5-flash          | Google Generative Language       |
| Grok       | grok       | grok-3-mini               | xAI OpenAI-compatible endpoint   |
| OpenRouter | openrouter | google/gemma-3-4b-it:free | OpenRouter chat completions      |

The model selector also receives a code-maintained list of supported choices from `_PROVIDER_MODELS`; the configured `model` remains the fallback for each provider.

## Client

### Client Fields

| Field        | Type        | Default   | Description                                                                     |
|--------------|-------------|-----------|---------------------------------------------------------------------------------|
| storage      | Element     | Empty     | Optional <code>state_key</code> attribute reserved for client storage selection |
| temperature  | Decimal 0-2 | 0.7       | Client evaluation preference                                                    |
| url_fetch    | Boolean     | false     | Client URL-fetch preference                                                     |
| thought_free | Boolean     | false     | Client thought-free preference                                                  |
| ui           | Section     | See below | Browser layout and interaction preferences                                      |
| providers    | Section     | See below | Provider/model selection and API keys                                           |

### UI Preferences

| Field                | Type                 | Default    | Description                      |
|----------------------|----------------------|------------|----------------------------------|
| layout               | horizontal, vertical | horizontal | Main panel arrangement           |
| theme                | system, light, dark  | light      | Color theme                      |
| divider_pos          | Integer 0-100        | 0          | Saved tree/chat divider position |
| swipe_nav_horizontal | Boolean              | true       | Horizontal swipe navigation      |
| swipe_nav_vertical   | Boolean              | false      | Vertical swipe navigation        |
| confirm_actions      | Boolean              | false      | Confirm destructive operations   |

### Client Provider Settings

| Field            | Type   | Purpose                                                         |
|------------------|--------|-----------------------------------------------------------------|
| default_provider | String | Selected provider name; must match a server provider definition |
| default_model    | String | Selected model override                                         |
| provider/name    | String | Provider name associated with a key                             |
| provider/api_key | String | Client-owned key for that provider                              |

```

<client>
  <temperature>0.7</temperature>
  <url_fetch>false</url_fetch>
  <thought_free>false</thought_free>
  <ui>
    <layout>horizontal</layout>
    <theme>light</theme>
    <divider_pos>0</divider_pos>
    <swipe_nav_horizontal>true</swipe_nav_horizontal>
    <swipe_nav_vertical>false</swipe_nav_vertical>
    <confirm_actions>false</confirm_actions>
  </ui>
  <providers>
    <default_provider>WikiOracle</default_provider>
    <default_model>nanochat</default_model>
    <provider>
      <name>WikiOracle</name>
      <api_key>...</api_key>
    </provider>
  </providers>
</client>

```

### Runtime Selection Precedence

| Setting               | Resolution order                                                                         |
|-----------------------|------------------------------------------------------------------------------------------|
| Provider              | Request config.provider -> client.providers.default_provider                             |
| Model                 | Request config.model -> client.providers.default_model -> selected server provider model |
| Main-provider API key | Request/runtime client provider key -> loaded client.providers.<name>.api_key            |

| Setting                    | Resolution order                                                                                                                                                                  |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dynamic truth-provider key | Embedded provider-entry key (literal or allowlisted <code>file://</code> ) -> matching configured provider key -> selected provider-family environment fallback where implemented |
| Temperature                | Request <code>config.temp</code> -> <code>server.evaluation.temperature</code> , clamped to 0-2                                                                                   |

The browser stores the normalized config in both `sessionStorage` and `localStorage` for tab-close durability. In stateful mode, `POST /config` accepts only the incoming `client` section; the server section remains authoritative on disk. Stateless servers reject config writes.

## Runtime Environment Variables

These variables configure the Flask process and its transport. XML still supplies provider definitions and model defaults.

| Variable                        | Default                                     | Purpose                                                             |
|---------------------------------|---------------------------------------------|---------------------------------------------------------------------|
| WIKIORACLE_STATE_FILE           | <code>state.xml</code>                      | Canonical state path                                                |
| WIKIORACLE_BASE_URL             | <code>http://127.0.0.1:8000</code>          | Local WikiOracle/NanoChat base URL fallback                         |
| WIKIORACLE_API_PATH             | <code>/chat/completions</code>              | Local upstream path                                                 |
| WIKIORACLE_BIND_HOST            | <code>127.0.0.1</code>                      | Flask bind interface                                                |
| WIKIORACLE_BIND_PORT            | <code>8888</code>                           | Flask bind port                                                     |
| WIKIORACLE_SSL_CERT             | Host-derived path under <code>~/.ssl</code> | TLS certificate                                                     |
| WIKIORACLE_SSL_KEY              | Host-derived path under <code>~/.ssl</code> | TLS private key                                                     |
| WIKIORACLE_TIMEOUT_S            | <code>120</code>                            | General provider timeout                                            |
| WIKIORACLE_MAX_STATE_BYTES      | <code>20000000</code>                       | Flask request/state size cap                                        |
| WIKIORACLE_MAX_CONTEXT_CHARS    | <code>40000</code>                          | Merge-context rewrite cap                                           |
| WIKIORACLE_MAX_INPUT_LEN        | <code>50000</code>                          | Chat-message character cap                                          |
| WIKIORACLE_REJECT_SYMLINKS      | <code>true</code>                           | Reject symlinked state files                                        |
| WIKIORACLE_AUTO_MERGE_ON_START  | <code>true</code>                           | Import adjacent <code>llm_*.xml/.json</code> files at startup       |
| WIKIORACLE_AUTO_CONTEXT_REWRITE | <code>false</code>                          | Append merge deltas to context                                      |
| WIKIORACLE_MERGED_SUFFIX        | <code>.merged</code>                        | Suffix for imported files                                           |
| WIKIORACLE_ALLOWED_ORIGINS      | Local HTTPS origins                         | CORS allowlist                                                      |
| WIKIORACLE_API_TOKEN            | Empty                                       | Optional bearer token                                               |
| WIKIORACLE_SESSION_SECRET       | Derived from state path                     | Flask session signing secret                                        |
| WIKIORACLE_RATE_LIMIT_CHAT      | <code>30</code>                             | Chat requests per minute per IP; 0 disables the chat-specific limit |
| WIKIORACLE_RATE_LIMIT_DEFAULT   | <code>120</code>                            | Default requests per minute per IP                                  |
| WIKIORACLE_STATELESS            | <code>false</code> fallback                 | Stateless fallback when CLI/XML do not decide                       |
| WIKIORACLE_URL_PREFIX           | Empty                                       | Route-prefix fallback                                               |

`OPENAI_API_KEY`, `ANTHROPIC_API_KEY`, and `GEMINI_API_KEY` are last-resort fallbacks for matching dynamic truth-provider URLs. Main provider calls use the canonical `client.providers` key flow.

## OpenClaw Extension

The `openclaw` submodule includes `extensions/wikioracle`, which invokes `bin/wo` and registers a provider, `/wo` command, and `wikioracle_query` tool.

| Field                  | Default                             | Purpose                                                 |
|------------------------|-------------------------------------|---------------------------------------------------------|
| <code>woPath</code>    | <code>../bin/wo</code>              | WikiOracle CLI path                                     |
| <code>serverUrl</code> | <code>https://127.0.0.1:8888</code> | Flask server URL                                        |
| <code>insecure</code>  | <code>true</code>                   | Skip verification for the local self-signed certificate |
| <code>stateful</code>  | <code>true</code>                   | Use the server-owned state contract                     |
| <code>stateFile</code> | <code>state.xml</code>              | Local file used for stateless state or stateful logging |
| <code>token</code>     | <code>None</code>                   | Optional bearer token                                   |

## CLI Flags

```
python bin/wikioracle.py [--config PATH] [--debug] [--stateless]
                        [--no-ssl] [--url-prefix PREFIX]
                        [serve | merge FILE...]
```

| Flag/command                     | Purpose                                                      |
|----------------------------------|--------------------------------------------------------------|
| <code>--config PATH</code>       | Load a specified configuration file                          |
| <code>--debug</code>             | Enable verbose diagnostic output                             |
| <code>--stateless</code>         | Disable writes and require client-owned request state/config |
| <code>--no-ssl</code>            | Serve plain HTTP instead of local TLS                        |
| <code>--url-prefix PREFIX</code> | Prefix all application routes                                |
| <code>serve</code>               | Start the Flask shim (default)                               |
| <code>merge FILE...</code>       | Merge portable state files into the canonical state          |

The authoritative schema is `data/config.xsd`.

## State

WikiOracle state is a portable XML document managed by `bin/state.py` and described by `data/state.xsd`. The canonical local filename is `state.xml`; the shipped example is `data/state.xml`.

## Grammar

```
State      -> Header + Conversation* + Truth?
Conversation -> title + (Message | Conversation)*
Message     -> content + attachment*
Truth       -> (Fact | Feeling | Reference | Logic | Provider | Authority)*
```

| Top-level element                 | Cardinality  | Purpose                                                     |
|-----------------------------------|--------------|-------------------------------------------------------------|
| <code>&lt;header&gt;</code>       | Exactly one  | Versioning, document identity, client label, and timestamps |
| <code>&lt;conversation&gt;</code> | Zero or more | Recursive conversation roots                                |
| <code>&lt;truth&gt;</code>        | Zero or one  | Typed TruthSet entries                                      |

```
<?xml version="1.0" encoding="UTF-8"?>
<state xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:noNamespaceSchemaLocation="state.xsd">
  <header>...</header>
  <conversation id="c_root">...</conversation>
  <truth>...</truth>
</state>
```

UI preferences and provider selection are configuration, not canonical XSD state fields. They live under `<config><client>`; see `Config`. For migration compatibility, `bin/state.py` still normalizes and round-trips a legacy runtime `ui` dictionary under the state header. That compatibility extension is not declared by `data/state.xsd` and should not be used in newly authored schema-conformant state files.

## Header

| Field                          | Type             | Required | Description                                             |
|--------------------------------|------------------|----------|---------------------------------------------------------|
| <code>version</code>           | Positive integer | Yes      | State grammar version (currently 2)                     |
| <code>schema</code>            | String           | Yes      | Schema URL or accepted <code>state.xsd</code> reference |
| <code>time_creation</code>     | String           | Yes      | Creation timestamp                                      |
| <code>time_lastModified</code> | String           | No       | Last serialized timestamp                               |
| <code>title</code>             | String           | Yes      | Portable state title                                    |
| <code>client_name</code>       | String           | No       | Display name attached to user messages                  |
| <code>client_id</code>         | String           | No       | Stable client identifier                                |

```
<header>
  <version>2</version>
  <schema>https://raw.githubusercontent.com/arborrhythms/WikiOracle/main/data/state.xsd</schema>
  <time_creation>2026-07-15T10:00:00Z</time_creation>
  <time_lastModified>2026-07-15T10:05:00Z</time_lastModified>
  <title>Research session</title>
  <client_name>Alice</client_name>
  <client_id>alice-uuid-123</client_id>
</header>
```

## Conversations

Each conversation contains one `<title>` followed by any number of direct `<message>` and nested `<conversation>` children. The on-disk order preserves the order in which messages and branches appear.

### Conversation attributes

| Attribute             | Required | Description                                                                 |
|-----------------------|----------|-----------------------------------------------------------------------------|
| <code>id</code>       | Yes      | Unique conversation identifier                                              |
| <code>parentId</code> | No       | Parent ID or comma-separated parent IDs for a diamond/merge node            |
| <code>selected</code> | No       | Boolean selection marker; selected conversations form one root-to-node path |

## Message structure

| Field/attribute                 | Required | Values or type                                                   | Description                                                                 |
|---------------------------------|----------|------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <code>id</code>                 | Yes      | String                                                           | Unique message identifier                                                   |
| <code>role</code>               | Yes      | <code>user</code> , <code>assistant</code> , <code>system</code> | Message role                                                                |
| <code>username</code>           | Yes      | String                                                           | Display label for the author/provider                                       |
| <code>time</code>               | Yes      | String                                                           | Message timestamp                                                           |
| <code>selected</code>           | No       | Boolean                                                          | Unique selected-message marker across the state                             |
| <code>&lt;content&gt;</code>    | Yes      | XHTML                                                            | Renderable message content                                                  |
| <code>&lt;attachment&gt;</code> | No       | Repeated element                                                 | Inline data or a URL, with optional <code>name</code> and <code>type</code> |

```

<conversation id="c_root" selected="true">
  <title>Animals</title>
  <message id="m1" role="user" username="Alice" time="2026-07-15T10:00:01Z">
    <content><p>Are dogs mammals?</p></content>
  </message>
  <message id="m2" role="assistant" username="WikiOracle" time="2026-07-15T10:00:02Z">
    <content><p>Yes. Dogs are mammals.</p></content>
    <attachment name="taxonomy.svg" type="image/svg+xml" url="https://example.org/taxonomy.svg"/>
  </message>
  <conversation id="c_breeds" parentId="c_root" selected="true">
    <title>Dog breeds</title>
  </conversation>
</conversation>

```

### Tree and DAG behavior

| Operation       | Runtime helper                                                          | Result                                                          |
|-----------------|-------------------------------------------------------------------------|-----------------------------------------------------------------|
| Find a node     | <code>find_conversation()</code>                                        | Recursive lookup by ID                                          |
| Resolve context | <code>get_ancestor_chain()</code> / <code>get_context_messages()</code> | Ordered messages from root through the active node              |
| Continue        | <code>add_message_to_conversation()</code>                              | Append a message to an existing node                            |
| Branch          | <code>add_child_conversation()</code>                                   | Insert a child conversation                                     |
| Delete          | <code>remove_conversation()</code>                                      | Remove a subtree                                                |
| Vote/merge      | Shared child plus multiple <code>parentId</code> values                 | Diamond-shaped DAG that remains navigable from each beta branch |

The serializer deduplicates a shared DAG node by ID. The `parentId` list preserves the logical multiple-parent relationship even though XML nesting has one emitted location.

### TruthSet

The optional `<truth>` element contains typed entries. Common metadata appears as attributes on each truth element.

### Common attributes

| Attribute | Applies to                | Required | Description                 |
|-----------|---------------------------|----------|-----------------------------|
| id        | Every truth kind          | Yes      | Unique entry ID             |
| title     | Every truth kind          | No       | Human-readable label        |
| time      | Every truth kind          | No       | Timestamp                   |
| place     | Every truth kind          | No       | Location metadata           |
| DoT       | Every kind except feeling | Yes      | Degree of Truth on [-1, +1] |

### Truth kinds

| Element     | Content model                      | Purpose                                                            |
|-------------|------------------------------------|--------------------------------------------------------------------|
| <fact>      | Mixed XHTML/text                   | Verifiable claim or observation                                    |
| <feeling>   | Mixed XHTML/text                   | Subjective expression outside the truth lattice                    |
| <reference> | Exactly one <a href="...">         | External citation                                                  |
| <logic>     | One and, or, not, or non child     | Strong Kleene/fuzzy derivation over <ref> or inline operands       |
| <provider>  | Provider-specific child fields     | Dynamic expert, optionally producing a visible conversation branch |
| <authority> | URL plus optional refresh interval | Remote TruthSet/state source                                       |

```

<truth>
  <fact id="t_dogs" title="Dogs are mammals" DoT="1.0">
    Dogs are mammals.
  </fact>

```

### Operator arity

| Operator   | Operands    | DoT result                       |
|------------|-------------|----------------------------------|
| <b>and</b> | Two or more | Minimum operand DoT              |
| <b>or</b>  | Two or more | Maximum operand DoT              |
| <b>not</b> | Exactly one | Negated DoT                      |
| <b>non</b> | Exactly one | $1 - 2 * \text{abs}(\text{DoT})$ |

See Logic for the interpretation and completeness argument.

### Provider entry fields

| Field               | Required | Meaning                                                                  |
|---------------------|----------|--------------------------------------------------------------------------|
| <b>api_url</b>      | No       | Dynamic provider endpoint                                                |
| <b>api_key</b>      | No       | Literal key or supported indirection used by dynamic-provider resolution |
| <b>model</b>        | No       | Model override                                                           |
| <b>system</b>       | No       | XHTML system instruction                                                 |
| <b>authority</b>    | No       | Nested URL and optional refresh configuration                            |
| <b>conversation</b> | No       | Whether the contribution appears as a conversation branch                |
| <b>timeout</b>      | No       | Request timeout                                                          |
| <b>max_tokens</b>   | No       | Response-token cap                                                       |

### Truth Evaluation and Persistence

| Phase                      | Entry kinds                                  | Behavior                                                     |
|----------------------------|----------------------------------------------|--------------------------------------------------------------|
| Direct truth               | Facts, feelings, references                  | Converted to source records for the provider bundle          |
| Derived truth              | Logic                                        | Recomputes DoT from the current operand entries              |
| Dynamic truth              | Providers, authorities                       | Consults experts or imports bounded remote evidence          |
| Server truth merge         | Resolved facts and logic                     | Optional moving-average merge into <b>data/truth.xml</b>     |
| Excluded from server truth | Feelings, providers, references, authorities | Must be resolved or intentionally omitted before persistence |

The server truth corpus accepts either a **<truth>** root or a **<state>** document containing **<truth>**. It is separate from the client's complete state file.

### Runtime Representation

`xml_to_state()` normalizes XML into a Python dictionary. Conversations use `messages[]` and `children[]`; truth entries use a stable envelope (`id`, `title`, `trust`, `content`, and optional metadata). Selection attributes are also exposed through helper fields such as `selected_conversation` and `selected_message`.

| XML surface                                       | Runtime shape                                                              |
|---------------------------------------------------|----------------------------------------------------------------------------|
| Recursive <b>&lt;conversation&gt;</b><br>children | Nested <code>conversations[]</code> / <code>children[]</code> dictionaries |

| XML surface                                          | Runtime shape                              |
|------------------------------------------------------|--------------------------------------------|
| Typed truth element name                             | XHTML/XML in <code>entry["content"]</code> |
| DoT attribute                                        | Numeric <code>entry["trust"]</code>        |
| Conversation/message<br><code>selected="true"</code> | Per-node flags plus derived selected IDs   |

## Serialization and Merge

| Function                                      | Purpose                                                                |
|-----------------------------------------------|------------------------------------------------------------------------|
| <code>state_to_xml(state)</code>              | Serialize normalized state to typed XML                                |
| <code>xml_to_state(text)</code>               | Parse typed XML into normalized state                                  |
| <code>load_state_file(path)</code>            | Load XML or a legacy monolithic JSON state                             |
| <code>atomic_write_xml(path, state)</code>    | Write through a temporary file, <code>fsync</code> , and atomic rename |
| <code>ensure_minimal_state(state)</code>      | Add required defaults and normalize tree/selection fields              |
| <code>merge_llm_states(base, incoming)</code> | Merge portable state with deterministic collision-safe IDs             |

The authoritative schema is `data/state.xsd`. Legacy JSON imports remain supported for migration, but newly persisted state is XML.

## User Interface

### Rendering

The display layer covers HTML structure, CSS classes, D3 node shapes, optimistic UI, and state persistence.

### Context for the upstream LLM

When a message is sent, the server needs to provide conversational context to the upstream model. The function `get_context_messages(conversations, conv_id)` walks the **ancestor chain** from the active conversation up to the root, collecting all messages in chronological order.

```
Root conversation      -> messages: [m1, m2, m3]
  |- Child conv        -> messages: [m4, m5]
    `-- Grandchild     -> messages: [m6, m7]  <- active
```

Context sent to LLM: [m1, m2, m3, m4, m5, m6, m7]

This gives the LLM the full path of dialogue that led to the current point, without noise from sibling branches.

### Tree visualisation (D3)

`tree.js` renders the conversation tree as a top-down hierarchy using `d3.tree()`:

```
conversationsToHierarchy(state.conversations, selectedId)
  ↓
D3 hierarchy data { id, title, messageCount, questionCount, selected, children }
  ↓
renderTree(hierarchyData, callbacks)
  ↓
SVG with nodes (rects/pills/circles) + curved links
```

The root node is a circle labelled /. Selected conversations render as larger labelled rectangles; others as compact pills. The selected node is highlighted with the accent colour.

## Chat view

`wikioracle.js` → `renderMessages()` displays the messages of the currently selected conversation:

1. Look up `selectedConvId` in the tree via `findConversation()`
2. Iterate `conv.messages`, rendering each as a `.message` div with role-based styling
3. Attach drag-to-reorder (HTML5 drag/drop) and right-click context menus to each message
4. Re-render the D3 tree in sync

When no conversation is selected (root view), a placeholder prompts the user to type.

## Rendering pipeline (end to end)

```
state.xml on disk
  ↓ [xml_to_state]
In-memory state with nested conversation tree
  ↓ [GET /state]
Client receives state payload
  ↓ [renderMessages]
Chat panel shows selected conversation's messages
  ↓ [conversationsToHierarchy]
D3 hierarchy data
  ↓ [renderTree]
SVG tree visualisation
```

## Interactions

### Tree panel

| Gesture                  | Action                                                      |
|--------------------------|-------------------------------------------------------------|
| Click                    | Navigate – select that conversation, show its messages      |
| Double-click             | Open context menu (Branch, Delete)                          |
| Right-click              | Open context menu (same)                                    |
| Drag node → drop on node | Merge – append source's messages into target, remove source |

A 200ms timer disambiguates click from double-click. Context menus are appended to `document.body` with fixed positioning to avoid clipping by the tree container's `overflow: hidden`.

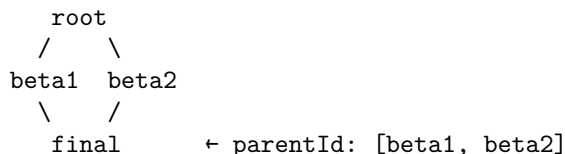

### Keyboard navigation

| Key         | Action                               |
|-------------|--------------------------------------|
| Arrow Up    | Navigate to parent conversation      |
| Arrow Down  | Navigate to first child conversation |
| Arrow Right | Next node in inorder traversal       |
| Arrow Left  | Previous node in inorder traversal   |

Keyboard events are ignored when a text input, textarea, or select element has focus, or when the context overlay is active.

**Diamond traversal** A diamond (DAG merge) occurs when a conversation has multiple parents (e.g. the final synthesis in an HME vote that merges two beta branches):

Arrow Right / Arrow Left perform standard tree preorder traversal. In a DAG the same node appears under multiple parents; it is visited **once per parent** so that each parent’s subtree is a complete reading path:

```

→ root → beta1 → final
→ beta2 → final → END

```

### Chat panel

| Gesture             | Action                                    |
|---------------------|-------------------------------------------|
| Right-click message | Context menu (Move up, Move down, Delete) |
| Drag message        | Reorder within the conversation           |

### Merge semantics

Dragging conversation A onto B:

1. Appends A’s messages after B’s existing messages (preserving order)
2. Re-parents A’s children under B
3. Removes A from the tree

### Branching

Double-click or right-click a tree node → “Branch” creates a new empty child conversation. The next message typed seeds it. The LLM receives the full ancestor context.

## Settings Dialog

The Settings panel (gear icon in the sidebar) configures client identity, provider/model selection, provider trust, layout, theme, and evaluation preferences. The normalized config is persisted under the `wikioracle_config` key in both `sessionStorage` and `localStorage`. Conversation state uses the separate `wikioracle_state` key.

### Settings Controls

| Control (DOM id)                                    | Value / default                                    | Storage and behavior                                                                                                         |
|-----------------------------------------------------|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Username<br>( <code>setUsername</code> )            | Text; <b>User</b>                                  | <code>state.client_name</code> ; display name attached to user messages                                                      |
| Provider ( <code>setProvider</code> )               | Select; shipped<br><b>WikiOracle</b>               | <code>config.client.providers.default_provider</code> ;<br>active main provider                                              |
| Model ( <code>setModel</code> )                     | Select; selected<br>provider’s<br>configured model | <code>config.client.providers.default_model</code> ; explicit<br>model override                                              |
| Provider trust<br>( <code>setProviderTrust</code> ) | Range 0-1; 0 when<br>absent                        | Browser copy of <code>config.server.providers.&lt;name&gt;.trust</code> ; runtime trust metadata for provider-produced truth |
| Layout ( <code>setLayout</code> )                   | Select; <b>horizontal</b>                          | <code>config.client.ui.layout</code> ; horizontal or vertical<br>panels                                                      |

| Control (DOM id)                                     | Value / default                      | Storage and behavior                                                                                         |
|------------------------------------------------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Theme ( <code>setTheme</code> )                      | Select; <b>system</b> UI fallback    | <code>config.client.ui.theme</code> ; system, light, or dark palette                                         |
| Temperature ( <code>setTemp</code> )                 | Range 0-2; server evaluation default | <code>config.client.temperature</code> ; sampling temperature                                                |
| Allow URL fetching ( <code>setUrlFetch</code> )      | Checkbox; <b>false</b>               | <code>config.client.url_fetch</code> ; client evaluation preference                                          |
| Thought-free mode ( <code>setThoughtFree</code> )    | Checkbox; <b>false</b>               | <code>config.client.thought_free</code> ; request non-discursive output and the BasicModel thought-free path |
| Confirm deletes / merges ( <code>setConfirm</code> ) | Checkbox; <b>false</b>               | <code>config.client.ui.confirm_actions</code> ; confirm destructive operations                               |

## Settings Persistence

| Setting family                                                      | Stateful mode                                                                                             | Stateless mode                                                                                |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <code>state.client_name</code> and <code>conversations/truth</code> | State is updated through <code>/state</code> or <code>/chat</code> ; browser keeps a local copy           | Browser state is authoritative and accompanies every <code>/chat</code> call                  |
| <code>config.client.*</code>                                        | Saved locally, then POST <code>/config</code> replaces the client section in the writable config override | Saved only in browser storage; POST <code>/config</code> is rejected                          |
| <code>config.server.*</code>                                        | Refreshed from <code>/config</code> ; client POSTs cannot replace it                                      | Included in the authoritative <code>runtime_config</code> returned by bootstrap/local storage |
| Provider metadata/model lists                                       | Refreshed from <code>/config</code> or <code>/bootstrap</code>                                            | Stored with the normalized config bundle                                                      |

Truth weight, concrete-fact storage, maximum truth entries, and training parameters remain available in the XML config/editor but are not separate controls in the current Settings panel.

## Server TruthSet Display

In debug mode, when online training is enabled, the client displays server TruthSet entries alongside local truth entries.

| Treatment   | Value                                 |
|-------------|---------------------------------------|
| Left border | 3px accent blue                       |
| Badge       | <b>SERVER</b> in small uppercase text |
| Opacity     | 0.65                                  |

Server truth entries are injected from the `/chat` response's `server_truth` field (debug mode only) and deduplicated by `id` on each refresh.

## User Interface Strings

Canonical UI text for the WikiOracle client. A consistency test (`test/test_ui_strings.py`) periodically checks that the strings hard-coded in `client/util.js` match the tables below.

## Truth editor

### Dropdown labels

| Key       | Label                                       |
|-----------|---------------------------------------------|
| feeling   | Feeling: subjective, non-verifiable claim   |
| fact      | Fact: disprovable assertion about the world |
| reference | Reference: citation with external link      |
| authority | Authority: pointer to remote TruthSet       |
| provider  | Provider: external LLM endpoint             |

### Descriptions

| Key       | Description                                                      |
|-----------|------------------------------------------------------------------|
| feeling   | Feeling -- a subjective, non-verifiable claim (not penalizable). |
| fact      | Fact -- a disprovable assertion with a degree of truth.          |
| reference | Reference -- a citation linking to an external source.           |
| and       | AND -- true when all children are true (min trust).              |
| or        | OR -- true when any child is true (max trust).                   |
| not       | NOT -- negation of a child entry.                                |
| non       | NON -- non-affirming negation (weakens trust toward zero).       |
| provider  | Provider -- an LLM API endpoint.                                 |
| authority | Authority -- a remote knowledge base (XML URL).                  |

### Templates

| Key       | Template                                                                                                                                              |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| feeling   | <code>&lt;feeling&gt;Subjective statement here.&lt;/feeling&gt;</code>                                                                                |
| fact      | <code>&lt;fact trust="0.0"&gt;Assertion text here.&lt;/fact&gt;</code>                                                                                |
| reference | <code>&lt;reference trust="0.0"&gt;&lt;a href="https://example.com"&gt;Link text&lt;/a&gt;&lt;/reference&gt;</code>                                   |
| and       | <code>&lt;logic&gt;&lt;and&gt;&lt;ref id=""/&gt;&lt;ref id=""/&gt;&lt;/and&gt;&lt;/logic&gt;</code>                                                   |
| or        | <code>&lt;logic&gt;&lt;or&gt;&lt;ref id=""/&gt;&lt;ref id=""/&gt;&lt;/or&gt;&lt;/logic&gt;</code>                                                     |
| not       | <code>&lt;logic&gt;&lt;not&gt;&lt;ref id=""/&gt;&lt;/not&gt;&lt;/logic&gt;</code>                                                                     |
| non       | <code>&lt;logic&gt;&lt;non&gt;&lt;ref id=""/&gt;&lt;/non&gt;&lt;/logic&gt;</code>                                                                     |
| provider  | <code>&lt;provider trust="0.0"&gt;&lt;api_url&gt;https://api.example.com&lt;/api_url&gt;&lt;model&gt;model_name&lt;/model&gt;&lt;/provider&gt;</code> |
| authority | <code>&lt;authority trust="0.0"&gt;&lt;url&gt;https://example.com/state.zip&lt;/url&gt;&lt;key&gt;password&lt;/key&gt;&lt;/authority&gt;</code>       |

### Empty state

| Key         | Text                                                       |
|-------------|------------------------------------------------------------|
| truth_empty | No truth entries. Add truth here or Open a new state file. |

# Proposed License

## WikiOracle Licensing Architecture

This document proposes a licensing structure for the WikiOracle project designed to preserve software freedom, maintain an open knowledge commons, and enable responsible AI development.

### Four-Layer Conceptual Model

WikiOracle separates artifacts into distinct licensing domains.

| Layer    | Artifact type           | Recommended license |
|----------|-------------------------|---------------------|
| Layer 1  | Software / engine code  | GPL-3.0             |
| Layer 2  | Human knowledge content | CC BY-SA 4.0        |
| Layer 3  | Structured data         | CC0                 |
| Layer 3B | Model weights           | Apache-2.0          |

Conceptual summary:

| Artifact | Encodes           |
|----------|-------------------|
| Code     | Algorithms        |
| Data     | Facts             |
| Weights  | Learned structure |
| Content  | Explanations      |

This layered separation mirrors successful open knowledge systems while extending them for AI systems.

### License Comparison Table

| License      | Domain                     | Key Features                                                        | Typical Use                   |
|--------------|----------------------------|---------------------------------------------------------------------|-------------------------------|
| GPL-3.0      | Software                   | Strong copyleft, patent protection, source distribution requirement | Infrastructure software       |
| CC BY-SA 4.0 | Creative works             | Attribution required, derivatives must remain under same license    | Wikipedia articles            |
| Apache-2.0   | Software / model artifacts | Permissive reuse with patent grant                                  | AI models and developer tools |

### GPL-3.0

Properties:

- strong copyleft protection
- requires publication of source code
- includes explicit patent protection
- prevents proprietary forks of infrastructure

## **CC BY-SA 4.0**

Properties:

- allows copying and adaptation
- requires attribution
- derivatives must remain under the same license
- widely used for collaborative knowledge projects

## **Apache-2.0**

Properties:

- permissive reuse
- explicit patent protection
- compatible with commercial ecosystems
- widely used for machine learning artifacts

## **Rationale for Layered Licensing**

### **Software (GPL-3.0)**

The WikiOracle engine should remain permanently open. GPL ensures that improvements to the infrastructure remain open-source and cannot be captured by proprietary forks.

### **Knowledge Content (CC BY-SA)**

Human-authored knowledge should remain part of a global commons. CC BY-SA ensures attribution and share-alike behavior so improvements remain public.

### **Structured Data (CC0)**

Structured datasets (truth graphs, semantic relations, dataset exports) benefit from minimal legal friction. CC0 allows unrestricted reuse and avoids attribution chains that complicate machine learning workflows.

### **Model Weights (Apache-2.0)**

Model weights are derived artifacts produced by training. Apache-2.0 allows redistribution, fine-tuning, and commercial use while providing patent protection.

## **Training Data Provenance Policy**

AI systems increasingly require transparent documentation of training sources.

WikiOracle should maintain a provenance record including:

- dataset origin
- license compatibility
- ingestion date
- preprocessing steps
- contributor identity (if applicable)

This allows:

- legal defensibility
- reproducibility
- verification of training inputs

Example provenance record structure:

dataset\_name  
source\_url  
license  
date\_ingested  
transformation\_pipeline

Provenance tracking supports both transparency and scientific reproducibility.

## AI-Generated Content Policy

AI-generated text occupies a hybrid authorship category.

WikiOracle should treat generated content in three stages:

| Stage                      | License  |
|----------------------------|----------|
| Raw AI output              | CC0      |
| AI draft edited by a human | CC BY-SA |
| Human-authored content     | CC BY-SA |

Rationale:

- raw AI output may lack clear authorship
- human editorial involvement establishes attribution
- share-alike preserves the knowledge commons

All AI contributions should record metadata:

generation\_model  
timestamp  
human\_editor  
revision\_history

This ensures transparency regarding machine involvement.

## Summary

WikiOracle licensing stack:

| Layer | Domain            | License      |
|-------|-------------------|--------------|
| 1     | Software          | GPL-3.0      |
| 2     | Knowledge content | CC BY-SA 4.0 |
| 3     | Structured data   | CC0          |
| 3B    | Model weights     | Apache-2.0   |

The architecture protects the software commons, maintains a global knowledge commons, and supports open AI development.
